

Systems Reference Library

IBM 1130/1800 Macro Assembler Programming

This manual describes how to use the Macro Assembler of the 1130 Disk Monitor System, Version 2, and the 1800 Multiprogramming Executive Operating System, Versions 2 and 3. It should be used by programmers who have a basic knowledge of the assembler language and use this language to write programs for these systems.

This publication is supplemental to the 1130 and 1800 Assembler Language manuals and should be used in conjunction with them. This manual describes the 1130/1800 Macro Assembler: the definition and usage of the macro instruction, features of macro and assembler-language programming, and creation of a language for a specific need; the Macro Update Program; and the error messages, error flags, and warning flags of the Macro Assembler and Macro Update Program.

First Edition (June, 1970)

This edition applies to the IBM 1130 Disk Monitor System, Version 2, and the IBM 1800 Multiprogramming Executive Operating System, Versions 2 and 3, and to all subsequent versions and modifications until otherwise indicated in new editions or Technical Newsletters. Significant changes and/or additions to the specifications contained in this publication are being made from time to time; therefore, before using this publication in connection with IBM systems, consult the latest SRL Newsletter, Order Number GN20-1130 or Order Number GN20-1800, for editions that are applicable and current.

Requests for copies of IBM publications should be made to the IBM Branch Office serving your locality.

Forms are provided at the back of this publication for the reader's comments. If the forms have been removed, comments may be addressed to IBM Corporation, Programming Publications, Department D78, Monterey and Cottle Roads, San Jose, California 95114.

Preface

This publication is a guide for assembler-language programmers of the 1130 Disk Monitor System, Version 2, or the 1800 Multiprogramming Executive Operating System, Version 3. It is supplemental to, and should be used in conjunction with, the 1130 and 1800 Assembler-Language manuals.

The first chapter, "Introduction," discusses the fundamentals of the Macro Assembler: what it is, how it operates, how much main storage it requires, how fast it performs, what types of macros there are, how to incorporate macros into your system; and, briefly, the Macro Update Program and error detection.

The second chapter, "The Macro Instruction," discusses how to define and use a macro instruction.

The third chapter, "Macro Assembler Features," discusses conditional assembly pseudo-operations, the ANOP, SET, and PURG pseudo-operations, automatic name generation, concatenation, optional remarks, indirect parameter substitution, the division operator, and the symbolic tag field. At the end of this chapter is a section on programming techniques. This section includes a sample program and programming tips. The sample program is for 1800 MPX but is also valid for the 1130 (an 1130 DM2 sample program is in Appendix A).

The fourth chapter, "Macro Assembler Language," describes how the Macro Assembler can be used to create a language for a specific purpose. The example is for the 1800 MPX system but is a general illustration that is also valid for 1130 users.

The fifth chapter, "The Macro Update Program," describes how you can set up and maintain your macro libraries through various statements. These statements may refer to whole libraries, macros within the libraries, or statements within the macros.

The sixth chapter, "Errors and Warnings," discusses the various error messages, error flags, and warning flags you may receive when using the Macro Assembler and the error messages you may receive when using the Macro Update Program.

Marginal notes have been included in this publication to allow easy reference to matter within the text.

The coding forms used in this manual are: for Macro Assembler statements, the 1130/1800 Assembler Coding Form, Order Number GX33-8000; for other statements, the General Purpose Card Punching Form, Order Number GX20-8030.

Required Reading

1130 publications:

Assembler Language manual, Order Number GC26-5927

1800 publications:

Assembler Language manual, Order Number GC26-5882

System Introduction, Order Number GC26-3718

Suggested Reading

1130 publications:

Disk Monitor System, Version 2, Programming and Operator's Guide, Order Number GC26-3717, for information on the Disk Utility Program and Macro Assembler control statements and error messages.

1800 publications:

Programmer's Guide, Order Number GC26-3720, for information on the Disk Management Program and Macro Assembler control statements.

Error Messages and Recovery Procedures manual, Order Number GC26-3727, for information on the warning flags, error codes, and error messages.

The 1130/1800 Macro Assembler

- condensing sequences The 1130/1800 Macro Assembler allows you to condense a sequence of assembler-language coding that you use over and over again into one instruction, a macro instruction.
- general-izing sequences If you use the Macro Assembler, you can generalize a sequence of coding and then modify it slightly each time it is used. You code the sequence only once, defining macro parameters that cause the appropriate code to be generated for a particular use. The exact code generated when the macro instruction is used is based on the conditional assembly, automatic name generation, and/or parameter substitution facilities of the Macro Assembler.
- creating a language The Macro Assembler also allows you to define a language that is unique to your application; such a language may be simple and/or meaningful enough to be used by a person other than a professional programmer.

THE MACRO INSTRUCTION

- defining a macro A macro instruction, or macro, is a source program statement. When the Macro Assembler encounters a macro, it expands the macro by processing a sequence of assembler-language statements. This sequence must have been defined in a macro definition before it can be used.
- types When you define a macro, you specify its operation code (macro name), its parameters, and the sequence of assembler-language statements to be processed when the Macro Assembler encounters the macro name in a source program.
- types Using the Macro Assembler, you can define two kinds of macros, temporary macros and stored macros. You should define every macro as a temporary macro until you are sure that it will execute properly. If it does execute properly, and you want to store it, you can include it in a macro library.

TEMPORARY MACROS

- use of temporary macros A temporary macro can be used only during the assembly of the program in which it is defined. This kind of macro isn't saved by the system; if you want to use it in another program, you have to define it again during assembly of that program. You do not have to define stored macros in order to use temporary macros.
- N2 If temporary macros are to be defined, you will need an *OVERFLOW SECTORS control statement. Two new parameters, N2 and N3, have been added to this statement. The N1 parameter remains the same. N2 is the number of sectors you allocated for the overflow of macro parameters from main storage to

disk. This parameter can be zero, and space will not be required if the overflow from a macro that is defined or called with another macro definition never exceeds 100 words. The required size of N2 may be estimated by using the following formula:

estimating

$$\text{Number of words} = 3 + N + \sum_{i=1}^N 1/2 (m_i + 1)$$

N3

N is the number of parameters and m_i is the number of characters per parameter. For example, the call
 EXPND ALPHA,BETA,C would be computed as
 $3 + 3 + 1/2(5+1) + 1/2(4+1) + 1/2(1+1) = 12$ words; the remainders of individual terms are ignored. N3 is the number of sectors you allocated for temporary macro definitions. You can estimate the number of sectors needed by dividing the total number of statements in all macro definitions within the assembly by 40. If you want to retain remarks, you may have to increase N3 to accommodate them. For further information on the *OVERFLOW SECTORS statement, see the 1130 Programming and Operator's Guide, Order Number GC26-3717, or the 1800 Programmer's Guide, Order Number GC26-3720.

estimating

STORED MACROS

use of
stored
macros

A stored macro, on the other hand, resides on disk in a macro library and can be used by any program. When you assemble a program that uses or defines stored macros, you must specify which macro library you wish to use during the assembly with the *MACLIB Macro Assembler control statement.

macro
libraries

The macro library specified on the *MACLIB statement must be defined and initialized before it can be used by the Macro Assembler. For details on how to initialize a macro library, refer to the discussion on initializing disk space in the chapter "The Macro Update Program." The *MACLIB statement enables you to access one library selectively without having to access all of the stored macros. Multiple macro libraries may be accessed in one assembly if you logically concatenate the libraries before the assembly. Additional information on macro libraries may be found in the chapter on the Macro Update Program.

use an
*MACLIB
statement

You cannot define a stored macro within an assembly unless you have used an *MACLIB statement. If your program attempts to call a stored macro which cannot be found in the specified library, the macro call will be flagged as an illegal operation. The format of the *MACLIB is as follows:

1-10										11-20										21-30										31-40									
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0
*MACLIB LNAME																																							

LNAME is the name of the macro library to be used in the current assembly. For further information on the *MACLIB statement, see the 1130 Programming and Operator's Guide, Order Number GC26-3717, or the 1800 Programmer's Guide, Order Number GC26-3720.

PSEUDO-OPERATIONS

definition

Pseudo-operations, or pseudo-ops, extend the capabilities of the assembly process. Pseudo-ops are written like assembler-language statements, but they are used to provide information to the Macro Assembler rather than to generate executable code for the program. They can appear anywhere within an assembler-language program, providing you follow the other rules for their use.

Several new pseudo-ops have been included for use in programs that use the Macro Assembler. These are described in detail under "Features of the Macro Assembler" and perform the following functions:

uses

- Defining the beginning and the end of a macro definition.
- Determining during an assembly whether certain statements are to be processed, based on a specific condition.
- Permitting a program label to be set to two or more different values at different points in a program without a multiple-definition error condition.
- Logically removing a macro from a library.

NESTED MACRO DEFINITIONS AND CALLS

A macro can be defined or called within another macro definition. This process is called nesting. The nesting of macro definitions is limited only by the physical size of your system. You may want to nest definitions to allow the dynamic definition (with decisions) of an inner macro when you are expanding the outer macro. This can also be used to advantage to conserve library space if the same code is being used in both macros (the inner one can be called only by the outer one).

The nesting of macro calls is limited to 20 calls per nest. You may wish to nest calls to macros so that values from one macro can be passed to the other macro.

MAIN-STORAGE REQUIREMENTS

THE 1130

The 1130

In the 1130 Disk Monitor System, Version 2, the Macro Assembler functions as and is fully compatible with the 1130 Disk Monitor System, Version 2, Assembler. However, the Macro Assembler requires 8K words of main storage for the macro capability. The symbol table in main storage has been reduced in size to accommodate approximately 750 words for the resident macro processor. Assemblies that almost

exhaust the symbol table area of the Assembler will probably require symbol table overflow sectors for successful assembly using the Macro Assembler (see the 1130 DM2 Programming and Operator's Guide, Order Number GC26-3717). The pseudo-operations SET, ANOP, AIF, and AGO (discussed later) are also available to the 4K 1130 user.

THE 1800

The 1800

The 1800 MPX Macro Assembler requires a VCORE of 5140 words. It occupies no more main storage than, and is fully compatible with, the 1800 MPX Version 1 Assembler.

MACRO ASSEMBLER PERFORMANCE

If you have a program that has been assembled successfully under the 1130 Disk Monitor Version 2 Assembler or the 1800 MPX Version 1 Assembler, the performance of the Macro Assembler will be approximately equal to that of the earlier Assemblers. Assembly time will be greater for new programs if the Macro Assembler encounters either a macro definition, a macro call, or an invalid op code. In the case of an invalid op code, the Macro Processor of the Macro Assembler will search the temporary macros and/or the specified macro library to determine whether the unrecognized op code is the name of a macro.

Macro Update Program

The Macro Update Program assists you in initializing and maintaining macro libraries. Using this program, you can add or delete macros from your library, alter those that are already in your library, physically or logically join two libraries, and perform other functions necessary to maintaining macro libraries.

Error Messages, Error Flags, and Warning Flag

During the assembly process, the Macro Assembler checks for source program errors. If an error is detected, an error flag or an error code and message are printed. If a questionable instruction is encountered, it is flagged with the warning flag (Q). At the end of each assembly, the Macro Assembler prints a message to indicate the number of errors and warnings it encountered during that assembly. Any errors in the Macro Update Program are detected by the Disk Utility Program (DUP) for the 1130 or the Disk Management Program (DMP) for the 1800.

The Macro Instruction

Defining a Macro Instruction

A macro definition can appear any time after the Macro Assembler has completed processing the control statements. The definition must appear before the first call to the macro.

MAC, SMAC
and MEND

The first statement in a macro definition in an assembly must be the MAC (for a temporary macro) or the SMAC (for a stored macro) statement. The last statement of a macro definition must be the MEND statement. The pseudo-op names MAC, SMAC, and MEND must appear in the op code fields of the statements.

No label and no operand are required on these statements. Column 35 of the MAC and SMAC statements can be used to specify that remarks are retained so that they can be printed on listings (see "Optional Remarks"). Note that if you exercise this option, you will need additional disk space to accommodate these remarks. Comment statements (* in column 21) within the definition are always retained and listed within the expansion.

THE DEFINITION PROTOTYPE STATEMENT

macro name

The statement immediately following the MAC or SMAC statement is called the definition prototype statement. This statement contains the macro name in its op code field. The macro name may be from one to five characters long. You cannot use a period, a comma, and a left or right parenthesis in macro names. A macro name can contain embedded blanks or can consist of all blanks. An invalid macro name is flagged as an illegal op code.

If you define a stored macro with a name that is already in the library named in the *MACLIB statement, it will be flagged as an invalid macro name. A temporary macro of the same name will not be flagged; it will be expanded when the macro is called since the temporary macros are searched before the stored macros. An apostrophe should not be used in the name of a stored macro because once this macro has been stored, it cannot be modified or removed from your library.

parameter
name

The label and operand fields of the definition prototype statement contain the names of parameters which are supplied when the macro is used. A parameter name can be any valid assembler-language symbol; an invalid parameter name is flagged as an op code error. You may use an op code as a parameter, but it must be done carefully because substitution will occur for all uses of the op code. Parameter names in the operand field are separated by commas. Do not include a blank within a parameter name or between parameters, as a blank terminates the parameter list. If the label field is blank, it is ignored when the macro is used. The definition prototype statement must

consist of one source statement; no continuation is allowed. A maximum of 20 parameter names is allowed.

definition

The text of the macro follows the definition prototype statement and is a sequence of assembler-language instructions, calls to other macros, and/or pseudo-ops. The statements in the text may contain the parameter names specified in the definition prototype statement. During assembly, the parameters specified in the call to the macro are substituted positionally for the corresponding parameter names in the text statements (see "An Example of Macro Definition"). Whenever the Macro Assembler prints macro definition prototype statements, five-digit decimal sequence numbers are printed to the left of each statement.

obtaining
a listing

The list control pseudo-operations (see the 1130 Assembler Language manual, Order Number GC26-5927, or the 1800 Assembler Language manual, Order Number GC26-5882) can be used within a macro definition to control the listing of a macro call. If you use an 1800, you may inhibit printing by turning sense switch 2 to the ON position.

parameter
sub-
stitution

You can substitute a parameter into any field or subfield of a text statement in the macro definition. A parameter substituted into the operand field of a text statement may be any valid assembler-language expression. The number of characters in the parameter name has no relationship to the number of characters actually substituted, except in the case of format and tag fields. Both the parameter name and the parameter substituted must be exactly one character long in order for the parameter to be substituted correctly into the format or tag field. Note that the number of characters in a parameter on a call may also be significant. For example, an increase in the number of characters caused by the substitution of longer parameters during the expansion may cause the operand field (columns 35-71) to be exceeded. Any information beyond column 71 will be ignored.

special
characters

The slash, comma, period, plus sign, minus sign, and asterisk retain their usual meaning. When a blank occurs in an operand field (except where permitted by the assembler language), the rest of the operand field is ignored. Special characters used in Macro Assembler statements must conform to the character code summaries as listed in the 1130 Assembler Language manual, Order Number GC26-5927, or the 1800 Assembler Language manual, Order Number GC26-5882.

AN EXAMPLE OF MACRO DEFINITION

The temporary macro SUM is completely defined by the following sequence. A definition of the macro SUM is shown below and the call and statements generated by the call are shown in the next section.

macro
definition

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
		MAC								
NAME		SUM				X, COUNT, LIST, STOR				
		LDX		X		-COUNT				
		SLA				1,6				
NAME		A		LX		LIST+COUNT				
		STO				STOR				
		MDX		X		1				
		MDX				NAME				
		MEND								

Using a Macro Instruction

calling
a macro

After a macro has been defined, you call it by using its name as an op code and specifying in the label and/or operand field the parameters to be substituted for the parameter names in the definition prototype statement. The parameter names must follow the order outlined under "The Definition Prototype Statement." If a parameter name is omitted (two commas in a row or a trailing comma), it is ignored when the macro is used.

When the Macro Assembler encounters a macro instruction, it processes the statements in the macro definition text with the parameters you have specified for substitution.

The assembled instructions are listed along with the macro call in the assembly listing. Any statement within a program that is a result of a macro expansion is flagged with a plus sign to the left of the label field of the Macro Assembler listing.

A sample definition of the macro SUM was illustrated in the previous section. Below is an example of a call to that macro, and the code generated by that call.

macro call

code
generated

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
LOOP		SUM				2, 10, FROM, TEMP				
		LDX		2		-10				
		SLA				1,6				
LOOP		A		L2		FROM+10				
		STO				TEMP				
		MDX		2		1				
		MDX				LOOP				

Parameters specified in the call to SUM are substituted for the dummy parameters of the SUM definition prototype statement. LOOP is substituted for NAME, 2 for X, 10 for COUNT, FROM for LIST, and TEMP for STOR. There's nothing special about the parameter in the label field of the call; it's substituted just like any other parameter. In fact, it need not even be used as a label in a macro definition; it can be used as an op code or an operand. For example, the macro DIVBY could be defined as follows (note that a while A appears in the label field of the definition prototype statement, it is used as an operand in the text of the macro):

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
漸										
漸		'DIY'	IDE			BY'	MACRO			
漸		A IS	DIV			IDED BY B				
漸		A AND	B			ARE SINGLE WORD VARIABLES				
漸										
		MAC								
A		DIVBY				B				
		LD				A				
		SRT				16				
		D				B				
		MEND								

When you call a macro, you may want to leave out one or more of the parameters. If the parameter to be left out would ordinarily be in the label field of the call, just leave it out. If the parameter would ordinarily appear followed by a comma in the operand field, leave out the character string to be substituted, but include the comma that would ordinarily follow the parameter. If the parameter ordinarily comes at the end of the operand field, you may leave it out. If you leave out one or more parameters that ordinarily come at the end, you may leave out all the commas that immediately precede them. If you anticipate omitting parameters that will be parts of AIF or AIFB expressions, refer to the section "Unspecified Parameter Checking" for restrictions on this operation.

8 1130/1800 Macro Assembler Programming

macro
definition

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		M A C													
		D C S				A	B	C							
		D C				A									
		D C				B									
		D C				C									
		M E N D													

The macro DCS generates DC statements. For example:

macro call

		D C S				1	2	3							
--	--	-------	--	--	--	---	---	---	--	--	--	--	--	--	--

would generate

code
generated

		D C				1									
		D C				2									
		D C				3									

Omitting parameter B in a call

macro call

		D C S				6		1	0	0	0				
--	--	-------	--	--	--	---	--	---	---	---	---	--	--	--	--

would cause

code
generated

		D C				6									
		D C													
		D C				1	0	0	0						

to be generated. Note that the operand of the second DC statement is blank because its associated parameter was omitted.

You should be extremely careful when omitting parameters because nothing is substituted for the parameter that is missing. Consider the following example; in the first call, the parameter is not missing and the code is generated properly. In the second call, the second parameter is missing and the generated code is in error.

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		M,A,C,													
macro		B,A,D,E,X				A,A,,B,B,,C,C									
definition		D,C				A,A									
		D,C				A,A+B,B+C,C									
		D,C				C,C									
		M,E,N,D													
		B,A,D,E,X				1,,2,,3									
macro call		D,C				1,									
		D,C				1,+2,+3									
code		D,C				3,									
generated															
		B,A,D,E,X				1,,,3									
macro call		D,C				1,									
		D,C				1,++3									
code		D,C				3,									
generated															

Substituting a Character String for a Parameter

You can substitute a character string containing embedded blanks and special characters (such as commas, periods, or slashes) for a macro parameter name by enclosing the string in parentheses. This makes it easy to pass a set of parameters to a nested macro call. However, you must be careful in passing character strings to ensure that parameters do not exceed the record length, as any information beyond column 71 will be ignored.

character
string
substitution

Assume in the example given below that SEE is a previously defined macro with a maximum of three parameters specified in the operand field. If another macro SCAN calls SEE, parameters may be passed to SEE as shown:

macro
definition

macro call

code
generated

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
*		'SCAN'				MACRO DEFINITION				
		MAC								
		SCAN				D, H				
		LD				D				
		SEE				H				
		MEND								
*										
		SCAN				TABLE, (VAL1, VAL3)				
*										
		LD				TABLE				
		SEE				VAL1, VAL3				

limits

Without this facility the same SCAN macro would have to be defined as follows in order to generate the above statement sequence. Notice that this second method may be restrictive in passing parameters, because a definition prototype statement may have no more than 20 parameters.

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
*		'SCAN'				MACRO DEFINITION				
		MAC								
		SCAN				D, H, I, J				
		LD				D				
		SEE				H, I, J				
		MEND								

in message
generation

You can also use character-string substitution to generate messages. An example of this is given below.

macro definition

macro call

code
generated

Label		Operation		F	T	Operands & Remarks					
21	25	27	30	32	33	35	40	45	50	55	60
*		'MSG'				MESSAGE	MACRO				
*		T IS				THE	CHARACTER	CODE	TYPE		
*		TEXT				IS	THE	MESSAGE	TEXT		
		SMAC									
		MSG				T	TEXT				
		DMES			T	'S'					
		DMES			T	TEXT	E				
		MEND									
*											
		MSG				1	(INVALID	CONTROL	STATEMENT)		
		DMES			1	'S'					
		DMES			1	INVALID	CONTROL	STATEMENT	E		

Continuing Calls to Additional Records

place a
character
in col. 32

A call to a macro may be too long to fit on one record, so the Macro Assembler allows calls to be continued onto one or more additional records. When you call a macro, you indicate that there is another record in the call by placing any character other than a blank in the format field (column 32). You can then continue the macro call beginning in column 35 of the next record. The first 31 columns of the next record are ignored; column 32, if used, specifies continuation of the call onto still another record.

Note that on continued calls, you must be careful in substituting parameters that have more characters than those in the original definition, because you may cause the operand field to be exceeded on either the CALL record or any subsequent continuation records. Therefore, some of your values may be lost (see "Macro Parameter Substitution" in the section on programming techniques).

When a macro call is continued onto an additional record, the Macro Assembler will stop its parameter scan of the first record when either there is a blank (not within parentheses) in the operand field or the operand extends to and includes column 71. The next character in your parameter list is assumed to be in column 35 of the next record.

replacing
consecutive
fields

Using parentheses and continuation records, you can replace any number of consecutive fields in a macro definition statement. Look at this example:

macro
definition

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
		MAC								
		ONION				A, B, C				
A		LD				XYZ				
		B								
		STO				C				
		MEND								

Here's a call to the ONION macro:

macro call

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
		ONIONS				(NAME	LD	ADDR	), (SRT	B)
						, (LOC	COMMENT)			

A punch other than a blank (the S in the above example) in the format field means that the macro call is continued on a second record.

The following code is generated from the above macro call.

code
generated

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
NAME		LD				ADDR		LD	XYZ	
		SRT				B				
		STO				LOC		COMMENT		

In the macro call, the instruction NAME LD ADDR replaces the label. The remaining fields, LD XYZ, are displaced to the right. The Macro Assembler treats these fields as remarks because in this example there are two blanks after ADDR.

This page intentionally left blank.

Macro Assembler Features

Conditional Assembly Pseudo-Operations

definition

You may want different calls to the same macro to produce different lines of assembled code, depending on some condition to be examined during the assembly. Conditional assembly pseudo-ops allow you to do this. These pseudo-operations do not generate any executable code and do not modify the address counter.

Applications which require slight code modifications to a general technique need be coded only once using conditional assembly pseudo-ops within macro calls. This saves time for the programmer.

AIF, AIFB PSEUDO-OPS

Two conditional-assembly pseudo-ops, the "assemble if" and "assemble if back" pseudo-ops AIF and AIFB, have the following format:

format

- An optional label.
- The op code (AIF, AIFB).
- In the operand field, a left parenthesis, an expression, one or more blanks, a condition, one or more blanks, another expression, a right parenthesis, a comma, and a name.

The two expressions can be any valid assembly expressions. The name should be a valid assembler-language symbol or may be left blank. It may also be any combination of from one to five characters if this combination is used in the label field of one of these pseudo-ops: AIF, AIFB, AGO, AGOB, ANOP, PURG, LIST, EJCT, HDNG, MEND, END, or SPAC. All symbols used within AIF or AIFB statement expressions must have been predefined or the statement will be flagged with a U (undefined symbol). If the name is left blank, the statement will be flagged with a warning flag (Q).

The condition must be one of the following:

conditions

- EQ-Equal to
- GT-Greater than
- LT-Less than
- NE-Not equal to
- GE-Greater than or equal to
- LE-Less than or equal to

AIF
function

During assembly, the condition statement between the parentheses is evaluated. If it is true, the AIF statement causes all the following statements to be skipped (and not processed) until the Macro Assembler finds a statement with a label corresponding to the symbol specified in the AIF statement. If the statement between the parentheses is false, the assembly continues with the statement immediately

following the AIF statement. The AIF statement may be used anywhere in a assembler-language program.

AIFB
function

The AIFB (AIF back) statement functions as the AIF statement, except that the Macro Assembler returns to the beginning of the current (innermost within a nest) macro definition being expanded (called) before searching for a label. Unlike the AIF statement, the AIFB statement may occur within a macro definition only; it is flagged as an illegal op code if it appears outside of a macro definition. If the search is unsuccessful, the MEND statement will terminate the search and the expansion of that macro.

if symbol
subfield
is blank

If the name subfield of the AIF or AIFB operand is left blank and the label search is to be performed, statements are skipped until the first statement with no label is encountered, at which time assembly continues. In any case, when a label search is performed, the search can continue until an END statement is encountered; the END statement will be processed and flagged with a Q. If the AIF statement is in a definition, a MEND statement will terminate the search.

Let's look at an example of the use of AIF.

AIF
example

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
		A I F				(X+1 EQ Y), SPOOK,				
		L D		L		PLACE				
		S T O		L		S P O T				
S P O O K		L D				G H O S T				
		S T O				W I T C H				
		A I F				(X+1 EQ Y)				
H O P E		M D X		1		1				
W H E E		M D X		2		1				
		M D X				S P O O K				

The assembly of this code depends on the values of X+1 and Y when the Macro Assembler evaluates them. If they are not equal, all the instructions shown above are processed. If they are equal, only the following three instructions are assembled.

results

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
S P O O K		L D				G H O S T				
		S T O				W I T C H				
		M D X				S P O O K				

Notice that the second AIF has a blank name field. As a result, the first instruction following this statement with a blank label field is assembled.

AGO, AGOB PSEUDO-OPS

Two other instructions are used along with AIF and AIFB to effect conditional assembly. These pseudo-ops, AGO and AGOB, cause unconditional branching and have the following format:

- format
- An optional label.
 - The op code (AGO, AGOB).
 - A valid assembler-language symbol or five blanks in the operand field. If the name field is left blank, the statement will be flagged with a warning flag (Q).

The name should be a valid assembler-language symbol, or may be left blank. It may also be any combination of from one to five characters if this combination is used in the label field of one of these pseudo-ops: AIF, AIFB, AGO, AGOB, ANOP, PURG, LIST, EJCT, HDNG, MEND, END, or SPAC.

AGO function

The AGO statement causes the Macro Assembler to skip (and not process) statements following the AGO statement until it encounters a statement with a label corresponding to the symbol specified in the AGO statement. See the ANOP section of this manual for an example of the use of the AGO instruction. The AGO statement may be used anywhere in an assembler-language program.

AGOB function

The AGOB (AGO back) statement functions as the AGO statement, except that the Macro Assembler returns to the beginning of the current (innermost within a nest) macro definition being expanded before performing the label search. If the search is unsuccessful, the MEND statement will terminate the search. Unlike the AGO statement, the AGOB statement may occur within a macro definition only; it is flagged as an illegal op code if it appears outside of a macro definition.

if symbol
subfield
left blank

If the operand of the AGO or AGOB statement is left blank and the label search is to be performed, statements are skipped until the first statement with no label is encountered. In any case, when a label search is performed, the search can continue until an END statement is encountered. Like the AGOB statement, if the AGO statement is in a definition, a MEND statement will terminate the search.

UNSPECIFIED PARAMETER CHECKING

The name searching technique used by the AIF and AGO pseudo-ops may be utilized in checking for unspecified parameters.

Assume that the COUNT parameter on the following prototype statement is a count of how many data words are to be moved from one area to another.

Label		Operation		F	T	Operands & Remarks				
21	25	27	30	32	33	35	40	45	50	55
		MAC								
		MOVE				FROM, TO, COUNT				
		AGO				COUNT				
		ANOP								
X		SET				1				
		AGO				BEGIN				
COUNT		ANOP								
X		SET				COUNT				
BEGIN		ANOP								
		.								
		.								
		.								
		MEND								

If COUNT is not specified in a call to MOVE, the name search prompted by the AGO COUNT statement will be terminated on the ANOP statement that follows immediately, because a blank was substituted for COUNT and the ANOP has a blank label field.

If COUNT is specified, the COUNT that is a label on an ANOP statement will be replaced with the COUNT specified in the call. Thus, the name search prompted by the AGO COUNT statement will terminate on the ANOP statement that has COUNT as a label.

SPECIAL CONSIDERATIONS USING AIFB AND AGOB

Note that if the AIFB or the AGOB causes a second assembly of the same code, multiple label definition errors may occur. It is your responsibility to ensure that the label to be skipped to is either unique or not entered in the symbol table, that is, a label on an AIF, AIFB, AGO, AGOB, SPAC, EJCT, HDNG, LIST, MEND, END, PURG, or ANOP statement. Also note that with the capability of the AIFB and AGOB, you can put the Macro Assembler into a loop. This will occur if the conditions never get changed, thus causing the Macro Assembler to loop between the AIFB and AGOB statements. The call below will cause the AIFB expression to be evaluated always as true (8 LE 20) because the AIFB to A will cause a branch to the first statement labeled A within the macro. Thus, the Macro Assembler will loop interminably between "A SET X" and the AIFB statement.

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		MAC													
DAY,		JOE				X,Y,Z									
A,		SET				X									
		DC				A									
A,		SET				A+Y									
		AIFB				(A LE Z), A									
		MEND													
*															
		JOE				6,2,20									

ANOP Pseudo-Operation

purpose

The purpose of the ANOP pseudo-op is to provide a label which an AIF, AGO, AIFB, or AGOB can reference to resume assembling. Assembling an ANOP label has the same effect as assembling the instruction immediately following it. The label on an ANOP is not placed in the symbol table, so statements other than AIF, AGO, AIFB, and AGOB can't use it as a reference. This is also true of other labels as discussed previously under "Special Considerations Using AIFB and AGOB."

The format of the ANOP statement is:

format

- A label.
- The op code ANOP.

The ANOP pseudo-operation allows you to associate temporary and permanent labels with the same instruction. Thus, the temporary label can be used to clarify a conditional assembly sequence while the permanent label can be used to clarify the instruction sequence.

The following is an example of a way in which ANOP might be used. In this example, A is assumed to have been defined prior to the AIF statement.

ANOP
example

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		A I F				(A , L T 0) , S K I P 1									
S E T 0 1		L D				I N T 0 1									
		A G O				S K I P 2									
S K I P 1		A N O P													
S E T 0 1		L D				I N T 0 2									
S K I P 2		A N O P													
		S T O				S W T C H									

When A is less than 0, the generated code is:

S E T 0 1		L D				I N T 0 2									
		S T O				S W T C H									

When A is greater than or equal to 0, the generated code is:

S E T 0 1		L D				I N T 0 1									
		S T O				S W T C H									

ANOP is useful when you're using the SET pseudo-op. An example of this usage is given in the "SET Pseudo-Operation" section.

SET Pseudo-Operation

purpose

SET allows you to assign a value to a symbol and, later in the assembly, assign another value to the same symbol without a multiple label definition error resulting. The symbol retains the value of the last SET statement associated with it from the first pass of the Macro Assembler until the Macro Assembler encounters an associated SET in the second pass. You can't use the EQU statement this way because the EQU statement is not processed on the second pass of the Macro Assembler and, consequently, cannot be used to change the value of a symbol during the assembly.

The format of the SET statement is:

format

- A label.
- The op code SET.
- A valid assembler-language expression in the operand field.

The label is set equal to the value of the expression in the operand field. Any symbols used within the expression on a SET statement must have been predefined, or the statement will be flagged with a U (undefined symbol).

Here's an example of the use of SET. Suppose A is the starting address of some data to be sent to disk, and B is the address of the end of the data. Assume we know the data will take up no more than two sectors and we want to set SECT equal to the number of sectors. The Macro Assembler automatically calculates the value of SECT in the following statement sequence.

SET
example

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
N		EQU				B - A									
K		SET				N - 320									
		AIF				(K, LE, 0), ONE									
SECT		SET				2									
		AGO				OK									
ONE		ANOP													
SECT		SET				1									
OK		(next instruction)													

In the above example, N, the difference between B and A, is compared to 320 by the AIF instruction. If the difference is greater than 320, the first SET following the AIF statement sets SECT to 2. The AGO then causes the assembly to continue around the next SET and the assembly proceeds.

If the difference (N) is less than or equal to 320, AIF causes the assembly to continue at ONE. This is equivalent to a continuation at the second SET following the AIF statement, since ONE is an ANOP instruction. Notice that it is impossible to branch directly to the correct SET instruction, since two SET instructions in the sequence contain the label SECT. If the AIF statement specified a branch to SECT, the Macro Assembler would continue processing with the next statement having SECT in its label field--in this case, the wrong instruction.

Here's another example of a macro that uses SET.

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		MAC													
		TAB				A, B, C									
X		SET				A									
NAME		AIF				(X, GE, C), ON									
		DC				X									
X		SET				X * B									
		AGOB				NAME									
ON		MEND													

Given variables A and B, the TAB macro defines a constant equal to A times B. It next defines a constant equal to this product times B. It continues this way until the result reaches a specified value, C. Note that if A and B are equal, TAB builds a table of powers of B.

PURG Pseudo-Operation

purpose

The PURG pseudo-operation removes the specified macro name from the macro library associated with the assembly by the *MACLIB control statement. PURG causes operations to occur only on the library associated with the *MACLIB control statement; it does not affect any other library even if it has been concatenated to the associated library (see MUP section on "Joining Macro Libraries Logically").

You can then define another macro with the same name, but the space occupied by the purged macro isn't available for reuse until the next DMP/DUP macro update job is performed on the library (see "Macro Update Program"). The space is reclaimed by any macro update function run on that library.

The format of the PURG statement is:

format

- Optional label (can be used as a target for pseudo-ops).
- Op code PURG.
- Macro name in the operand field.

The macro name must be enclosed in apostrophes (the first apostrophe must be in column 35). If the macro name is not properly formatted, is missing, or cannot be found, the PURG statement will be flagged with a warning flag (Q) and the PURG operation will not be performed.

Automatic Name Generation

purpose

If your macro definition contains a label that isn't a parameter of the macro, and if you call the macro more than once in a given assembly, you'll get a multiple-definition error for that label. You can get around this problem by making all labels used in macros parameters of the macros, but then you have to supply all the labels every time you call a macro. An easier method to use is automatic name generation.

use an
apostrophe

Instead of writing out a complete label in the macro definition, you write from one to four alphameric characters, the first of which must be alphabetic, followed by an apostrophe. Each time a macro is called in a given assembly, the Macro Assembler replaces the apostrophe with a number--a different number each time.

generates
a five
character
label

The number of digits added to your label always causes a five character label to be generated. For example, repeated uses of the label P' result in the labels P0001, P0002, P0003, and so on. Repeated uses of the label PAM' result in PAM01, PAM02, PAM03, and so on.

problems
in nested
macros

The digits inserted into your label by the above method are determined by a counter maintained by the Macro Assembler. When the Macro Assembler encounters a macro that utilizes the automatic name generation feature, the counter is

use an
apostrophe
before

The way around this problem is to place an apostrophe before the characters in the label. The Macro Assembler replaces this apostrophe with a different alphabetic character (beginning with A) each time a macro is called within a given nest. Thus, if the label 'RAB is used in a macro and the macro is called four times in the same nest, the labels generated are ARAB, BRAB, CRAB, and DRAB.

begin and
end with
apostrophe

You can use apostrophes at both the beginning and the end of a label; in fact, this is the simplest way of ensuring that you don't get multiply-defined labels. The label 'C' can result in labels from AC001 through TC999 (T rather than Z because only 20 levels of macro nesting are allowed). The label 'SPY' can result in labels from ASPY1 through TSPY9.

Note that if you alternately call macros with automatic name generation, the numbers of the generated labels will also alternate. For example, if you call two macros alternately and the first has a label C' and the second has a label D', the resulting labels would be C0001, D0002, C0003, D0004, and so on.

The Macro Assembler also automatically generates labels in the remarks field (not on comment records) of assembler-language statements. For this reason, you must be careful when using apostrophes within a remark.

Concatenation

period or
ampersand

By concatenating two parts of a field, you can join a parameter to a character string, two parameters, or two character strings. You can use either a period or an ampersand as a concatenator. The ampersand functions as a concatenator only if it appears as the first character in a parameter of a definition prototype statement. Otherwise, it functions as a plus operator. If you use the ampersand as a concatenator, you may use six characters, including the ampersand, for the parameter name.

period
example

The following example shows several uses of period concatenation.

macro
definition

Label		Operation		F	T	Operands & Remarks									
21	25	27	30	32	33	35	40	45	50	55					
		MAC													
NAM		MOVE				A	B	C	N	M	U				
		LDX			N	M									
X.NAM		LD.A		L	N	A	B	C							
		ST.B		L	N	B	B	C							
		MDX			N	-	U								
		MDX				X	N	A	M						
		MEND													

Using the above definition with the macro calls below, the code following the calls would be generated.

macro call

code
generated

macro call

code
generated

Label		Operation		F	T	Operands & Remarks												
21	25	27	30	32	33	35	40	45	50	55								
*																		
*		'MOVE'				MACRO	CALL											
*																		
FIRS		MOVE				,	0	,	2	S	,	1	,	5	,	1		
		LDX			1	5												
XFIRS		LD		L	1	A	B	2	S									
		STO		L	1	B	B	2	S									
		MDX			1	-	1											
		MDX				X	F	I	R	S								
ABLE		MOVE				D	,	D	,	L	1	,	3	,	1	8	,	2
		LDX			3	1	8											
XABLE		LDD		L	3	A	B	L	1									
		STD		L	3	B	B	L	1									
		MDX			3	-	2											
		MDX				X	A	B	L	E								

Notice that in the above examples, parameter substitution does not occur for A and B in the names AB.C and BB.C. You need to be careful when you are using any op code as a parameter, because substitution will occur for all uses of that op code.

ampersand
example

The following examples show several ways in which the ampersand can be used as a concatenator. Notice in the second example that the B in the macro definition is not preceded by an ampersand and, therefore, the B is a parameter, but the &B is not.

	Label		Operation		F	T	Operands & Remarks							
	21	25	27	30	32	33	35	40	45	50	55			
example 1			MAC											
			MOVE 1				B							
macro			LD				A	B						
definition			STO				B	B						
			MEND											
macro call	*													
			MOVE 1				X	Y	Z					
code generated			LD				A	X	Y	Z				
			STO				B	X	Y	Z				
example 2	*													
			MAC											
macro			MOVE 2				B							
definition			LD				A	B						
			STO				B	B						
			MEND											
macro call	*													
			MOVE 2				X	Y	Z					
code generated			LD				A	B	X	Y	Z			
			STO				X	Y	Z	B	X	Y	Z	

Because a period is used frequently as a decimal point when writing DEC and XFIC statements, the Macro Assembler inhibits period concatenation when writing these statements. The ampersand concatenation feature may still be used.

Optional Remarks

retaining
remarks

When you define a macro, you specify whether or not you want remarks on the macro definition statements to be reproduced each time the macro is expanded. If you want to keep the remarks, place any nonblank character in column 35 of the MAC or SMAC statement. The disk space required for the macro is increased according to the amount of space required for your remarks. Comment statements within the definition are always retained and listed within the expansion.

parameters
in remarks

If parameters occur in remarks, parameter substitution is performed for the remarks also. This substitution includes automatically-generated names. The Macro Assembler also substitutes parameters into comments statements (asterisk in column 21), but it does not substitute automatically-generated names into comments statements. On such statements, the apostrophe is treated like any other character.

All records are truncated following column 71 of the record, and no error indication is given.

Indirect Parameter Substitution

The indirect parameter substitution feature allows you to substitute one parameter for another when a macro is expanded. You do this by specifying a semicolon followed by any valid assembler-language expression, instead of the parameter you wish to replace, in the macro call.

use a
semicolon

The value of this expression is evaluated by the Macro Assembler and is considered to be the position of the replacement parameter in this macro call. For example, if the expression is evaluated as 3, the parameter in the third position is the replacement parameter. Remember, in determining the position of the replacement parameter, the label field of the call is the first parameter.

deter-
mining
position

The position number and semicolon are counted as one parameter. If the replacement parameter position referenced is not specified in the macro call, an empty parameter is substituted. An indirectly-specified parameter may select as many as 19 other indirectly-specified parameters. If this limit is exceeded, an empty parameter is substituted, and the macro call is flagged with a syntax error indicator. Processing continues with the next statement.

If a symbol within a parameter substitution specification is not defined before its use, the substituted expression is evaluated as zero, the referenced parameter is evaluated as a blank parameter, and processing continues.

syntax
errors

The following examples demonstrate the use of indirect parameter substitution.

examples

	Label		Operation		F		T	Operands & Remarks				
	21	25	27	30	32	33		35	40	45	50	55
macro definition			M A C									
			B R T B					A				
			B S C		L			A				
			M E N D									
macro call			B R T B					; 4, LOC 1, LOC 2, LOC 3				
			B S C		L			LOC 2				
code generated												
macro call			S E T					1				
			B R T B					; A + 3, LOC 1, ; A + 5, LOC 2, LOC 3				
code generated			B S C		L			LOC 3				

In a nested macro call, if the symbol following the semicolon is a parameter of the outer macro, the parameter must be concatenated to the semicolon for recognition by the Macro Assembler. (Concatenation was described previously under "Concatenation.")

Division Operator

a slash

preceded
by a term

The Macro Assembler interprets any slash in the operand field as a division operator, unless it can be interpreted as a hexadecimal number indicator. A hexadecimal constant is indicated by a slash in column 35. A slash preceded by an operator is interpreted as the hexadecimal indicator. A slash preceded by a term is interpreted as a division operator. A division operator may be immediately followed by a + or - to indicate whether the divisor is positive or negative. If no + or - follows the division operator, the divisor is assumed to be positive. A division operator followed immediately by a multiplication operator is flagged as a syntax error (S). Division by the internal address register (IAR) is allowed in an absolute assembly; in a relocatable assembly, it is flagged as a relocation error (R).

Each division operation within each term is performed from left to right. The 16-bit quotient is the result of a division operation; the remainder is lost.

The Macro Assembler performs all operations in an expression algebraically. For example:

(1) $3+2*4/2 = 7$ (2) $5*2/3+9/-3 = 0$

In example 1 the entire term $2*4/2$ is evaluated from left to right before it is combined with 3. In example 2 the term $5*2/3$ is evaluated (left to right) first. Then the term $9/-3$ is evaluated and combined with the first term. Note that since the result of a division is always an integer with the remainder ignored, the first term in example 2 if written as $2/3*5$ would be evaluated as 0 but 3 would result when the term is written as $5*2/3$.

Note that division by zero results in a zero quotient and a warning flag. A relocation error flag (R) will be issued if either the dividend or divisor is relocatable. If two consecutive division operators are found in a single term, the term will be replaced by zero. For example, $27/9/3$ will not be correctly evaluated and will be replaced by zero; the statement in which it occurred will be flagged as a syntax error (S).

Symbolic Tag Field

purpose

If you wish to change an index register designation once you have coded that portion of your program, you can do this by using the symbolic tag field feature. You specify the tag field with a one-character symbol which is defined in the assembly by means of an EQU or SET statement (see the 1130 Assembler Language manual, Order Number GC26-5927 or the 1800 Assembler Language manual, Order Number GC26-5882).

in SET
pseudo-ops

You may change the value of the tag symbol dynamically when using the SET pseudo-operation to define the tag field. The tag symbol retains the value of the last SET statement associated with it from the first pass of the Macro Assembler until the Macro Assembler encounters an associated SET statement in the second pass. The EQU statement is not read on the second pass of the Macro Assembler and,

consequently, cannot be used to change the value of the tag symbol during assembly.

example

The following example illustrates use of the symbolic tag field in instructions and the code generated by those instructions.

source

Programming Techniques

The following items should help you in using the Macro Assembler.

CHECKING FOR BLANK PARAMETERS

It is generally desirable to simplify macro calls by defining macros so that parameters (preferably the last parameter in the call) may be optionally omitted. Passing a blank parameter to the macro can cause a special sequence of code or no code to be generated. This blank parameter in the call causes no substitution to occur for the parameter when the macro is expanded. Consider the following examples:

```

// JOB 01 JAN 70 00.504 HRS
// * EXAMPLE 1 SHOWS HOW A BLANK MACRO PARAMETER SUBSTITUTES
// * WHEN USED IN A MACRO CALL
// ASM SAMPL 01 JAN 70 00.505 HRS
*LIST
*OVERFLOW SECTORS ,1

0000      00001      MAC      C      BEGIN MACRO DEFINITION
                   APPLE    GOOD
                   DC      GOOD*5    CONSTANT DEFINED
                   MEND
                   EQU      *      END OF MACRO DEFINITION
*
*      THE FOLLOWING CALL TO APPLE
*      CAUSES A SYNTAX ERROR

000 ERROR(S) AND 000 WARNING(S) IN ABOVE ASSEMBLY.

```

The SET statement is used in Example 2 to avoid Macro Assembler errors that can result from passing blank parameters. Note the use of \$ in the label field. Use of \$, @, and # in macro labels may help prevent conflict with other labels used in the program. These characters may also be used in conjunction with the automatic name generation feature.

RESTRICTIONS ON AIF, AIFB, AND SET PSEUDO-OPERATIONS

We have said that symbols used either in the SET operand field or in the AIF or AIFB expression must have been defined before the referencing SET, AIF, or AIFB statement is processed. Since symbols used as above in AIF, AIFB, and SET are evaluated at the time they are first encountered, they are flagged with the U error even if the symbols are defined later in the program. This error flagging has been implemented to help ensure that code generated by SET, AIF,

or AIFB statements is the code intended by the user. See Example 3.

```
// JOB 01 JAN 70 00.517 HRS
// * EXAMPLE 3 ILLUSTRATES THE RESTRICTION ON THE AIF OPERATION
// * THAT A SYMBOL MUST BE DEFINED PRIOR TO ITS USE IN

LABEL AND BLANK PARAMETER CHECKING USING AGO

The Macro Assembler does not have an explicit method for character string comparison. However, the AGO and ANOP pseudo-operations provide a means of label checking both within and outside of a macro. Consider Example 4.

```
// JOB 01 JAN 70 00.525 HRS
// * EXAMPLE 4 ILLUSTRATES THE USE OF THE AGO AND ANOP OPERATIONS
// * TO HANDLE BLANK MACRO PARAMETERS WITHOUT CAUSING ASSEMBLER

002 ERROR(S) AND 000 WARNING(S) IN ABOVE ASSEMBLY.

MACRO PARAMETER SUBSTITUTION

When special features such as call continuation and indirect parameter substitution are used in nested macro calls you must account for such special instances as you code your macro. If, for example, you anticipate that a nested macro call may be a continued call, you must pass the continuation indicator and ensure that any parameter string from the first call is completed on each nested continuation record. See Example 6. If you wish to pass a symbolic value to a nested macro call and an indirect substitution expression and that symbol appears next to the semicolon, you must concatenate the symbol to the semicolon. See Example 7.

```

// JOB    01 JAN 70 00.561 HRS
// * EXAMPLE 6 ILLUSTRATES THE METHOD FOR HANDLING CONTINUATION OF
// * NESTED MACRO CALLS
// ASM SAMPL    01 JAN 70 00.562 HRS

① The 1 indicates the overflow sector necessary to house temporary macro definitions in this assembly.

② If CNT is less than or equal to 0, the definition is not expanded.

③ Sequence numbers of definition statements are printed for easier visual perception.

④ The move loop is generated with your program's parameters.

⑤ This AIF checks the call to the DCS macro to determine if you want a label to be associated with the first DC.

⑥ You can significantly alter a printed listing when a macro is called through use of the LIST pseudo-op.

⑦ All statements resulting from a macro expansion are flagged with a plus in column 20.

⑧ This is a call to DCS with the label specified.

⑨ Note how use of the LIST pseudo-op caused this expansion to be printed.

⑩ This is a call to DCS without the label specified.

⑪ LOOP1 illustrates the automatic name generation feature of the Macro Assembler. LOOP1 was named as LOOP' in the macro definition.

⑫ By using parentheses, the parameter TEXT (see the MSG definition) is replaced by a string of characters into a DMES statement.

NOTES

Macro Assembler Language

The features of the Macro Assembler permit you to create a language that can help programmers who are new to your installation or who don't understand the more detailed aspects of certain operations. This specialized language may also be used by programmers who know the operation and want to simplify their job or who need to interact with persons other than programmers. Such a specialized language may also be used to help others learn to write simple programs for your system.

Consider the following 1800 MPX example.

Mr. Jones is a programmer who works for a sports information service center and is in charge of all baseball statistics. He has been assigned the following project in response to a customer requisition.

SPORTS INFORMATION SERVICE CENTER

programmer: A.B. Jones
date needed: September 10, 1972

date submitted: September 7, 1972
customer: 126-3381-07

Problem:

1. Read a batch of data cards having the following format:

columns 1-20 Player's name
25-28 Number of at-bats
30-33 Number of singles
35-38 Number of doubles
40-43 Number of triples
45-48 Number of home-runs

2. Compute the player's batting average, slugging percentage, and home-run ratio.
3. Print all the information mentioned in 1 and 2.
4. Terminate execution of the program when a data card containing an asterisk (*) in column 1 is read.

Mr. Jones knows that in order to answer this request, he will have to use some macros from the general purpose library, use some macros from his own library, and use the following computations in his solution.

Batting average=number of hits number of times at bat.

For example, if hits=13 and at-bats=64, $13 \div 64 = .203$
The batting average would be .203.

Slugging percentage=(number of singles + 2 x number of doubles + 3 x number of triples + 4 x number of home runs) $\div$ number of at-bats.

For example, if at-bats=64, singles=8, doubles=3, triples=1, and home runs=1, the slugging percentage would be $[8+2(3)+3(1)+4(1)] \div 64$ or $21 \div 64$ or .328

Home run ratio=number of at-bats ÷ home runs.
 For example, if at-bats=64 and home runs=4, the home
 run ratio would be 64 ÷ 4 or 16.

Mr. Jones then looks in the guide to general purpose macros
 and determines which ones he wants to use. The guide lists
 the macros in a library that have been built by all the
 programmers who work with Mr. Jones. These macros are ones
 that are used frequently by the programmers, such as, read a
 card and print a line.

The following listing demonstrates how this library of
 macros was created. In this case the library has been named
 SYSTM.

```

21 27 35
 Format: LABEL DCBIN INPUT,OUTPUT
 This macro calls the DCBIN subroutine which converts
 a decimal value in 5 IBM card-coded characters and 1
 sign character to a 16-bit binary word.

21 27 35
 Format: LABEL BINDC INPUT,OUTPUT
 This macro calls the BINDC subroutine which converts
 a 16-bit binary number to its IBM card-coded decimal
 equivalent.

21 27 35
 Format: LABEL LLIST CNTRL,AREA,WDCNT
 CNTRL = control parameter
 AREA = address of the area to be worked upon
 WDCNT = word count of the I/O area
 This macro ("long list") generates a nine word I/O list
 which may be used with the various MPX I/O
 subroutines.

21 27 35
 Format: LABEL RDCRD LIST
 LIST = address of the associated 9-word I/O list
 This macro, used in conjunction with the LLIST macro
 or the SLIST macro which is shown below, calls the
 CARDN subroutine and also performs a busy test.

21 27 35
 Format: LABEL PRINT LIST
 LIST = address of the associated 9-word I/O list
 This macro, used in conjunction with the LLIST or
 SLIST macro, calls the PRNTN subroutine and
 performs a "busy" test.

21 27 35
 Format: LABEL HOLPR CNTRL,INPUT,OUTPT,CHRCT
 CNTRL = 0 if 1053 code is desired; 1 if 1442 is desired
 INPUT = address of the area to be converted
 OUTPT = address of the area which will contain the
 converted data
 CHRCT = number of characters to be converted
 This macro calls the HOLPR subroutine which converts
 an area from IBM card code (Hollerith) to either
 1443 or 1053 code.

21 27 35
 Format: LABEL SLIST CNTRL,AREA,LABL1,LABL2
 CNTRL = control parameter
 AREA = address of the area to be worked upon
 LABL1 = label (optional) of the control parameter DC
 LABL2 = label (optional) of the area parameter DC
 This macro ("short list") is similar to the LLIST in that
 a nine word I/O list is generated. It is different in that
 the word count and I/O area are not allocated and, also,
 that labels, if desired, may be placed on the control and
 area parameter DC statements. The SLIST macro would
 probably be used when it is desired at various points in
 a program to modify the control and/or area parameters.

He then determines which macros from his library, which he has named JONES, are required. This library contains macros that he has written because he finds them useful in his job of providing baseball statistics.

The following listing demonstrates how his library was created.

```

21 27 35
Format: LABEL MOVE FROM, TO, COUNT
FROM = address of the data to be transferred
TO = address at which the data will be transferred
COUNT = number of words to be transferred
The MOVE macro transfers a block of data from one area to another.

21 27 35
Format: LABEL SUM X, COUNT, LIST, STORE
X = index register to be used
COUNT = number of words to add
LIST = address of the first word to be added
STORE = address where the sum shall be placed
The SUM macro calculates the sum of a block of contiguous words and places the result into a word designated by a STORE parameter.

21 27 35
Format: LABEL BA AB, HITS, BAVG
AB = address of the word which contains the number of at-bats
HITS = address of the word which contains the number of hits
BAVG = address where the batting average shall be placed
The BA macro calculates a batting average and places it into a word designated by the BAVG parameter.

21 27
Format: LABEL CDEQU
The CDEQU macro generates a series of EQU statements tailored for the processing of data cards.
LABEL = address of the word count word which precedes the buffer into which a data card will be read
Since EQU statements do not increase the size (in words) of a program, it is not wasteful if all of the labels generated by CDEQU are not used.

21 27 35
Format: LABEL MPY NUMBR, BY, PROD
NUMBR = address of one number to be multiplied
BY = second number (not an address) to be multiplied
PROD = address of the word where the product will be stored
The MPY macro multiplies two given numbers and stores the result into a word designated by the PROD parameter.

21 27 35
Format: LABEL HRATE AB, HR, RESULT
AB = address of the word which contains the number of at-bats
HR = address of the word which contains the number of home-runs
RESULT = address where the home-run ratio will be stored
The HRATE macro calculates a home-run ratio and places the result into a word designated by the RESULT parameter.

21 27 35
Format: LABEL MSG1 TEXT, X
TEXT = text, using DMES syntax, of the message
X = 0 if 1053 message, 1 if 1443 message
The MSG1 macro facilitates the printing of a message. A word count and DMES statement are generated.

21 27 35
Format: LABEL MSG2 TEXT1, TEXT2, X
The MSG2 macro is the same as the MSG1 macro except that two DMES statements (for longer messages) are generated.

UPDATE COMPLETED

21 27 35
Format: LABEL CHECK CHK,TSTCH,LOC
CHK = address of the word to be checked
TSTCH = value of the word against which the check is made
LOC = "branch to" address for when the check shows the words are equal.
The CHECK macro compares a word against a test character and branches to LOC if the two words are identical.

21 27 35
Format: LABEL SPRSS CHAR,WITH,START,COUNT
CHAR = the value (character) to be suppressed
WITH = the value (character) to replace the suppressed character
START = address where suppression shall begin
COUNT = number of contiguous words to check for suppression
The SPRSS macro is used primarily to suppress leading zeros in a numeric field about to be printed. For example, it would facilitate printing 63 instead of 000063.

This allows Mr. Jones to have all the macros in his library available along with the system library, SYSTM.

Mr. Jones has now selected all the macros he is going to use, and the next step is for him to write the coding. The following is a list of the source coding Mr. Jones decided to use. Note that he could have further reduced the coding by using more complex macros. (In order to aid understanding, the macros in this sample are not complex; therefore, the coding required by Mr. Jones is far more extensive than would be needed in actual applications.)

PRINT FIRST LINE (MES1)

All macros in SYSTM and JONES may be used in this assembly.

Print the line **EXECUTE SAMPLE PROGRAM**.

GET ADDRESS OF MES2
SET UP I/O AREA PARAMETER
PRINT OUTPUT HEADINGS

Change the print I/O area parameter to point to the word count of the next line to be printed.

Print the second line: NAME,AB,1B, etc.

Assure that the word count preceding the card input buffer is 80. This is not necessary for the first card to be read, but is necessary for the reading of all ensuing cards since a 40 will be stored at CDBUF before printing a data card.

READ A DATA CARD

Read a data card into CDBUF.

Check the card just read for an asterisk in column 1 (* = /4220 in IBM card code) and branch to END if an asterisk is found.

WKBUF and WKBUF+1 contain an IBM card code (Hollerith) plus and zero respectively. The four columns (25 through 28) for at-bats are moved into the four-word buffer following WKBUF.

Converts the number of at-bats to a 16-bit binary value and stores the result into location ATBAT. (See the 1800 MPX Subroutine Library manual, Order Number GC26-3724, for further information on DCBIN.)

Move and convert the four columns for singles (30 through 33) and store the result into location SNGLS.

Move and convert the four columns for doubles (35 through 38) and store the result into location DBLES.

```

Suppress the first character in the slugging percentage field if it is a zero.

Suppress the first character in the home-run ratio field.

Convert the 80-word buffer CDBUF to 1443 printer code.

Set the print I/O area parameter to point to CDBUF which is from where the next line will be printed. Also set CDBUF to 40 (print word count).

Print a line of data.

Branch to process next card.

Generate an I/O list designed to read a card. Also, create a word count and an area into which the card may be read.

Generate a list of equates designed for data card handling.

Word area for DCBIN and BINDC manipulations.

General work area.

Generate an I/O list for printing which contains the desired control parameter and an area parameter pointing to the first printed line. Place a label on the area parameter word as it will be changed during execution.

Generate the word count and message of the first line to be printed.

Generate the word count and message of the second line to be printed.

0135 0 2000	+	MDX	00022	
0136 0 0000	+B0022	OC	/2000	
0137	+C0022	OC	0	
	+D0022	EQU	*	

Convert and move the home-run ratio to columns 60-63 of the card buffer.

Suppress leading zeros to facilitate an easy-to-read printout by replacing all leading zeros (/2000 in card code) with blanks (0 in card code). Do this for the at-bat field.

Suppress leading zeros in the singles field.

Suppress leading zeros in the doubles field.

Suppress leading zeros in the triples field.

Suppress leading zeros in the home-runs field.

Suppress the first character in the batting average field since batting averages are always written with 3 digits. (The first character will always be zero.)

END OF JOB

From this example you should realize how the use of macros with meaningful names helped Mr. Jones and his fellow workers make efficient use of their system. Similarly, you can design your macros and libraries to aid your programmers and others who must work with the programmers.

This page intentionally left blank.

The Macro Update Program

The Macro Update Program (MUP) assists you in maintaining macro libraries. It performs the following functions:

- Initializes disk space for macro libraries.
- Adds macros to libraries.
- Deletes macros from libraries and reclaims the space they occupied.
- Joins macro libraries, physically or logically.
- Renames macros.
- Obtains a listing of the contents of macro libraries by macro name or by macro name and statement.
- Inserts or deletes statement(s) within a macro.
- Provides macro definition source statements on cards.

calling
MUP

field
speci-
fications

To call the Macro Update Program, you must first load the Disk Utility Program (for DM2) or the Disk Management Program (for MPX) into main storage. After it has been loaded, you use an *MACRO UPDATE control statement to call MUP. Following this statement, you should use MUP control statements to indicate the functions you want to perform. The function field must begin in column one, and at least one blank is required to separate it from the operand field. If you leave the first column blank, the statement will be ignored. If you want to specify more than one operand, you must separate the operands by commas and leave no blanks within or between them. Any unused columns in MUP control statements are reserved for system use. With the exception of the NAME function (described later in this chapter), control statement continuation is not allowed in MUP.

Note that once a Macro Update function has been started, it should not be aborted, because an incompleting modification may cause the library to be unusable.

All special characters used in the Macro Update Program must conform to the character code summaries as listed in the 1130 Assembler Language manual, Order Number GC26-5927, or the 1800 Assembler Language manual, Order Number GC26-5882.

Initializing Disk Space

reserve
space

Before initializing disk space, you must reserve a data file to serve as your macro library. This can be accomplished by means of an *DFILE statement or an *STOREDATA statement. For a detailed description of *DFILE and *STOREDATA, see the Programming and Operator's Guide (for DM2), Order Number GC26-3717, or the Programmer's Guide (for MPX), Order Number GC26-3720.

To initialize disk space for a macro library, you must use a BUILD statement. The library name in the BUILD statement must be the same as the one defined in the *DFILE or *STOREDATA statement. After you have named a library, you must use that library's name in all LIB, BUILD, JOIN, or CONCAT statements (described later) that refer to that library. You must initialize disk space before requesting the Macro Assembler or the Macro Update Program to operate on a specific library. The format of a BUILD statement is as follows:

BUILD
format

1-10										11-20										21-30										31-40																																									
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4																												
BUILD										'LNAME'																																																													

LNAME is the name of the macro library that was reserved by the *DFILE or *STOREDATA statement (discussed above). LNAME is a 1-5 character name for the macro library. The apostrophes are delimiters and, as such, are required by MUP for the names of all macros and libraries. You can use alphabetic characters A-Z and the characters 0-9, #, @, and \$ within your library name. The digits 0-9 may not be used as the first character. A library name is considered a symbol, and therefore, it must conform to the rules for symbols as stated in the Assembler Language manual, Order Number GC26-5927 (for the 1130) or Order Number GC26-5882 (for the 1800). If LNAME applies to a previously initialized library containing macros, the function purges the library and reinitializes it.

Specifying the Macro Library

To specify the macro library to be operated on, you use the LIB statement. The format of a LIB statement is as follows:

LIB
format

1-10										11-20										21-30										31-40																																									
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4																												
LIB										'LNAME'																																																													

LNAME (discussed above) is the name for the macro library.

Joining Macro Libraries Physically

If you want to physically join a macro library to the end of the library specified in the last BUILD or LIB statement,

use JOIN

you use a JOIN statement. For example, if you wanted to physically join LIB06 to LIB05, you would use the following statements.

format

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1	LIB 'LIB05'																																										
2	JOIN 'LIB06'																																										
3																																											

contents
unchanged

These statements cause the contents of LIB06 to be added (physically copied) to the end of the contents of LIB05. This does not change the contents of library LIB06.

notes

If the first library cannot accommodate the library being joined to it, the JOIN operation is suppressed. Neither library is changed and processing continues with the next LIB or BUILD statement. If you specify a new library name in a BUILD and then join an existing library to it, you physically copy the existing library.

Joining Macro Libraries Logically

use CONCAT

If you want to logically join a macro library to the library specified in the last BUILD or LIB statement, you use a CONCAT statement. This statement allows you to maintain individual libraries, and then unite them for assembly purposes without using additional disk space.

purpose

For example, if you wanted to logically join LIB22 to LIB15, you would use the following statements.

format

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1	LIB 'LIB15'																																										
2	CONCAT 'LIB22'																																										
3																																											

multiple
concaten-
ation

These statements cause both libraries to be available for assembly purposes when LIB15 is referenced by the Macro Assembler. However, in any Macro Update Program operation, only the library named on the last LIB or BUILD statement is operated upon.

It is possible to concatenate a multiplicity of libraries, so that several libraries may be available to the Macro Assembler even though the assembly references only one. You

disconnect

format

The CONCAT statement would cause the library (LIB22) that has been concatenated to library LIB15 to be disconnected. The physical contents of the libraries remain unchanged.

Updating a Macro in a Library

If you want to alter a macro that has been stored in the library specified in the last BUILD or LIB statement, you specify that macro with the UPDATE function. An example of specifying the macro TAXES might be as follows.

use
UPDATE

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
LIB 'COSTS'																																											
UPDATE 'TAXES'																																											

Renaming a Macro in a Library

use
RENAME

If you want to rename a macro in a library, you use the RENAME statement. Once you have renamed a macro, the original name is lost, and the macro can be referenced only by its new name. The format for the RENAME statement is as follows:

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1 RENAME 'BOLTS', 'RIVET'																																											
2																																											

This statement would cause the macro BOLTS to be renamed RIVET. BOLTS represents the name of the current macro; it must be enclosed in apostrophes and separated from the new name by a comma. RIVET represents the new name for the macro. The macro must now be referenced by this new name. BOLTS can now be used as a name for another macro. The RENAME statement may be followed by INSERT or DELETE statements.

Defining a Macro During a Macro Update Run

You can define a macro during a macro update run by using essentially the same method you use during an assembly. The differences are that you don't use MAC or SMAC and MEND statements, and you don't use a definition prototype statement. Instead, you use a NAME statement to name the parameters to be used in a subsequent definition and an ADD statement to name the macro (discussed below). The format of the NAME statement is as follows:

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1 NAME P1, P2, P3, . . . , Pn																																											
2																																											

P1 is the symbol for parameter 1, P2 is the symbol for parameter 2, and so on.

Note that parameter 1 is the parameter used in the label field of the macro call. Parameter 2 would be the first parameter in the operand field. If you need more than one record for all your parameters (limited to 20 possible), use as many NAME records as needed immediately following the first, and continue the parameters on these records. In

such a case, a comma must not follow the last parameter on each record.

If your NAME statement does not have sufficient parameter names for the parameters in the macro being processed, one of the following will occur.

- On input, the additional parameters will be assumed to be standard Macro Assembler variables instead of macro parameters.
- On output, the operation will be aborted and a D117 error message printed. This also occurs if a parameter that is used in the format or tag fields is given a name that is greater than one character.
- On listing, extra parameters will be replaced by // N where N is the number (1-20) of the parameter. A D117 error message will be printed. Note that the parameter number may be truncated if it exceeds the field length.

The names specified in the NAME statement are used in all subsequent operations until the next LIB or BUILD statement is encountered or another NAME statement is read.

ADD STATEMENT

then ADD
statement

After the NAME statement, you use the ADD statement. The ADD statement adds the macro to the library specified in the last LIB or BUILD. The ADD statement in conjunction with the NAME statement performs the same function as the definition prototype statement of the Macro Assembler definition. The format of the ADD statement is as follows:

	1-10										11-20										21-30										31-40									
	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0
format	1	A	D	D																																				
	2																																							

This statement causes the macro PARTS to be added to the end of the macro library specified in the last BUILD or LIB statement.

Following the ADD statement, you place the assembler-language source statements that you want to include in the definition. The macro being thus defined by the ADD function is terminated by the occurrence of a MUP control statement. An example of how to define a macro during a macro update run is as follows:

1-10										11-20										21-30										31-40										
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4							
1	*MACRO UPDATE										call to Macro Update Program																													
2	LIB 'QUALI'										specifies library																													
3	NAME LABEL,T1,T2										specifies parameters (described above)																													
4	ADD 'TESTS'										adds and names macro																													
5											LD										T1																			
6											STO										T2																			
7	ENDUP										terminates MUP run																													
8																																								

lack of
room

If there is not sufficient space in the library to accommodate the macro you want to store, the macro is not added. Processing continues with the next LIB or BUILD statement; the library is not changed by this occurrence.

If you define another macro within a macro definition, then the MAC or SMAC and MEND statements of the nested macro are included in the definition of the outer macro. Thus, if a macro is defined with an ADD statement and its source statements include a MAC or SMAC and MEND statement, then every time it is called in an assembly, a macro definition is generated.

The definition prototype statement cannot be used in a macro defined by the ADD function except in conjunction with a MAC or SMAC statement. If one is present, no error is diagnosed. Note also that macro source statements stored during a MUP run are not diagnosed for errors.

Deleting a Macro From a Library

use PURGE

If you want to delete a macro from the library named in the last LIB or BUILD statement, you use a PURGE statement. This function deletes the macro that is specified, and automatically reclaims the space it occupied. The format of a PURGE statement is as follows:

format

1-10										11-20										21-30										31-40														
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	
1	PURGE 'WAGES'																																											
2																																												

This statement causes the macro `WAGES` to be deleted from the library named in the last `LIB` or `BUILD` statement and reclaims the space `WAGES` occupied.

PURGE
vs. PURG

The Macro Update Program `PURGE` statement should not be confused with the Macro Assembler `PURG` statement. The Macro Assembler `PURG` statement does not automatically reclaim the space occupied by the macro named in that statement. Instead, the space is reclaimed by running the Macro Update Program. Any macro update run affecting a particular library will reclaim the space occupied by a macro deleted from that library with the Macro Assembler `PURG` statement. The `PURG` and `PURGE` statements cause operations to occur in regard to the specific library named in the last `LIB`, `BUILD`, or `*MACLIB` statement. They do not affect any other library.

Punching Source Statements

use OUTPUT

If you want to punch the source statements of a specified macro definition, you can use the `OUTPUT` statement. This statement must have been preceded by a `NAME` statement. Blank cards must be available for punching as soon as the `OUTPUT` statement is read.

Care should be taken in preparing the `NAME` statement since the `OUTPUT` function will be aborted if a parameter is defined incorrectly or is left undefined (see `NAME` statement described previously). The definition to be punched must be part of the library specified in the last `LIB` or `BUILD` statement. The format of the `OUTPUT` statement is as follows:

format

1-10										11-20										21-30										31-40															
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4		
1	OUTPUT 'SALES'																																												
2																																													

`SALES` is the name of the macro definition to be punched. This statement also causes an `ADD 'SALES'` statement to be punched prior to the source statement to facilitate loading of the definition at a later time. The source statements will contain an identification (first three characters of the macro name) and a sequence number in columns 73-80.

Inserting a Statement in a Macro

use INSERT

If you want to insert additional macro definition source statements into a macro, you can use the `INSERT` statement. This statement must be preceded by a `RENAME` or `UPDATE` statement and a `NAME` statement (discussed previously) that specifies the macro to be modified and its parameters, and it must be followed by the source statements to be inserted. The format of an `INSERT` statement is as follows:

format

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1 INSERT NNNNN																																											
2																																											

NNNNN is a decimal integer (maximum of 32767) up to five digits long. It references a macro definition source statement sequence number. The source statements are inserted after NNNNN; so, if you want the statements inserted before any other statements in that macro, you must specify NNNNN as zero.

Whenever MUP or the Macro Assembler prints macro definition source statements, five-digit decimal sequence numbers are printed to the left of each statement. These sequence numbers are referenced by INSERT and DELETE statements. Any statements inserted into a library by the ADD, INSERT, or DELETE (described in the next section) function are flagged with an X when the definition is printed. Macro definition source statements are automatically sequenced when the ADD function is used, and resequenced when the INSERT or DELETE functions are used.

notes

You can insert only as many statements as the library has room for. In other words, if you have 25 statements to add to a macro, and there is enough space to accommodate only 15 of those statements, those fifteen statements will be added. A D103 LIBRARY OVERFLOW message will be printed; processing will continue with the next LIB or BUILD statement. If you want to include the ten statements left out of your macro after regaining enough space to accommodate them, you will have to alter your INSERT control statement because of the resequencing of the statements in the macro library that has occurred.

Deleting a Statement From a Macro

If you want to delete one or more statements from a macro, you can use the DELETE statement. The DELETE statement must be preceded by a RENAME or UPDATE statement that specifies the macro to be altered and a NAME statement (discussed previously) that specifies parameter names used for alteration. The format of a DELETE statement is as follows:

format

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1 DELETE MMMMM, NNNNN																																											
2																																											

MMMMM is the sequence number of the first source statement to be deleted and NNNNN is the sequence number of the last source statement to be deleted. This statement would cause the statements from MMMMM through NNNNN inclusive to be deleted. If you want to delete a single source statement, you can leave the comma and second parameter off or specify the first sequence number again.

A DELETE statement may be followed by source statements to be inserted in place of the deleted statements. You do not need to use an INSERT statement to perform this function. You may insert more or fewer statements than you deleted. If you insert statement(s), you can insert only as many as the library has room for. The Macro Update Program will insert as many as will fit, print an error message, and continue processing with the next LIB or BUILD statement.

Obtaining a Listing of Macro Libraries by Statements or Macros

The SELECT control statement is used to control the Macro Update Program printed output and remark inclusion. The output is always printed on the list (principal) printer, and MUP control statements are always printed. You can also specify in a SELECT statement that remarks are to be included with any macro text statement being placed on disk. An example of the print format may be seen in the sample program that is at the end of this chapter.

The format of the SELECT statement is as follows:

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
SELECT M, P, I, C, N																																											
1																																											
2																																											

no parameters--suppresses printing of macro headers and macro text.

M--causes headers to be printed.

P--causes text and headers to be printed. If you select this option, it should have been preceded by a NAME statement (discussed previously). On an OUTPUT operation with this option, the 1800 will not list the macro text. Note that if a LIB, BUILD, or ENDUP statement is encountered and no name statement is available, SELECT P will be reset and the text will not be printed. On the 1800, if sense switch 2 is ON, printing will be suppressed.

I--causes headers to be printed except during an ADD, INSERT, or DELETE operation, in which case, the macro headers and text are printed. If you do not specify a SELECT statement, I is assumed.

On the 1800, if sense switch 2 is ON, printing will be suppressed.

C--indicates that remarks are to be included with any macro text statement being placed on disk.

SELECT N

N--indicates that both of the following conditions are true (see also the section following):

- You want to update a nested definition.
- The statement(s) inserted uses the automatic name generation feature.

You may use any combination of parameters in a SELECT statement; however, I will override M and P will override either I or M, or both. Each two consecutive parameters must be separated by a comma, with no embedded blanks. If you use more than one SELECT statement, the latest is assumed, and the prior SELECT statements are overridden.

SPECIAL REQUIREMENTS ON THE USE OF AUTOMATIC NAME GENERATION IN NESTED DEFINITIONS

When automatic name generation is used with nested definitions, the indicators for automatic name generation (leading and/or trailing apostrophes) must be suppressed until the call (expansion) of the outer macro occurs. Otherwise, the automatic name generation feature will not function properly. To suppress this feature, the statements in a nested definition must be stored as data. In a nested definition, the MAC statement(s) of the inner nested definitions indicates that the Macro Update Program (on an ADD statement) or the Macro Assembler (on an SMAC statement) should store the statements between the MAC and its associated MEND.

When inserting statements that use automatic name generation in a nested definition, you must precede the INSERT or DELETE statements with a SELECT statement that includes N as one of its parameters. This should be done to indicate the Macro Update Program should store these inserted statements as data. The SELECT N option should be followed by another SELECT option (without N as a parameter) when all inserts to the nested definition are completed. If suppressing the automatic name generation feature by SELECT N is not done properly, the consequences will not be observed until an assembly with the call (expansion) of the nested macro is attempted.

Consider the following example:

```
LIB 'LIB01'  
SELECT P  
NAME LABEL,A,B,C
```

```
14BO 0005 MAC09  
00001 LABEL LD L A  
00002 STO L B  
00003 MAC  
00004 MOVE CNT, FROM, TO  
00005 LDX -CNT  
00006 A' LD L1 FROM+CNT  
00007 STO L1 TO+CNT  
00008 MDX 1 1  
00009 MDX A'  
00010 MEND  
00011 BSC L C  
00012 **MACRO END**  
14BO 0049 **LIBRARY END**  
0000
```

ENDUP

UPDATE COMPLETED

The macro MOVE is a nested definition and uses the automatic name generation feature. Hence, a SELECT N statement must precede any updates (statements for insertion into the macro MOVE) that use the automatic name generation feature. Failure to do so will result in the symbol actually being expanded at this time, which is not desired.

Note that any updates using automatic name generation outside the macro MOVE should not be preceded by a SELECT N statement, since the automatic name generation will be suppressed. In the above example, an insert that uses automatic name generation made between statement number 00003 and statement number 00010 should be preceded by a SELECT N statement. An insert made elsewhere in the macro MOVE that does not use automatic name generation should not be preceded by a SELECT N.

Designating Comments

use a
period

A period in column one of any record designates that record as a MUP comment and it is printed on the list (principal) printer. If, however, an error has occurred, and MUP is ignoring all statements until the next LIB or BUILD statement, comments will also be ignored and not printed. Note also that MUP comment records are never included in your macro library.

Terminating a Macro Update Run

use ENDUP

To terminate a Macro Update Program run properly, you must use an ENDUP statement. This statement must be the last MUP control statement used, or else none of the statements that follow it will be processed. You don't specify any parameters in an ENDUP statement; the format is as follows:

format

1-10										11-20										21-30										31-40													
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4
1	ENDUP																																										
2																																											
3																																											

The UPDATE COMPLETED message (see the following sample program, note 9) indicates that the Macro Update run has been properly terminated. This does not imply that all the operations requested were successful.

Sequencing MUP Control Statements

The following table illustrates the required order of MUP control statements. Each x in the matrix indicates that the function at the top of the column must precede the statement to the left side of the x. MUP statements not included in this table have no precedence requirements.

	BUILD or LIB	RENAME or UPDATE	NAME
LIBRARY FUNCTIONS			
JOIN	X		
CONCAT	X		
NAME STATEMENT	X		
MACRO FUNCTIONS			
UPDATE	X		
ADD	X		X
PURGE	X		
RENAME	X		
OUTPUT	X		X
STATEMENT FUNCTIONS			
INSERT		X	X
DELETE		X	X
PRINT FUNCTIONS			
ANY SELECT P			X

Note that a new LIB or BUILD function removes the previous NAME statement and a new one must be used. On any function where you use a SELECT P option, you must have a NAME statement available to SELECT P or else the print or punch operation will not be as you wanted it.

Making Efficient Use of the Macro Update Program

The Macro Update Program searches sequentially through the library it is operating on for the macro specified in a RENAME, OUTPUT, UPDATE, or PURGE statement. It joins

request
functions
in order

libraries and adds macros to the end of each library. Consequently, the printing may be voluminous while the Macro Update Program is positioning for the requested function. Therefore, to make the most efficient use of the program, you should request the macro functions in the order in which the macros appear in the library, and the JOIN and ADD functions after all other functions for that library have been performed.

For example, suppose LIB01 contains four macros: MAC1, MAC2, MAC3, and MAC4, respectively and you want to perform an OUTPUT function on MAC1 and MAC4, a PURGE function on MAC2, a RENAME function on MAC3, and a JOIN function on LIB02. The following statement sequence is the most efficient to perform these functions.

	1-10										11-20										21-30										31-40										4				
	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	
1	LIB 'LIB01'																																												
2	OUTPUT 'MAC1'																																												
3	PURGE 'MAC2'																																												
4	RENAME 'MAC3', 'GET'																																												
5	OUTPUT 'MAC4'																																												
6	JOIN 'LIB02'																																												
7	ENDUP																																												
8																																													

The concatenate function does not cause library positioning, and thus, its position within a MUP run is not important.

A Sample Macro Update Program

The following sample program illustrates a sample Macro Update Program run.

```

// JOB      X 00 JAN 00 00.012 HRS
// *        SAMPLE USAGE OF MACRO UPDATE PROGRAM (MUP)
// DMP      00 JAN 00 00.012 HRS

```

- 1 The library named in a BUILD statement must have been defined previously with an *DFILE control statement.
- 2 The NAME statement is required and may specify parameter names to be used in a subsequent definition.
- 3 **LIBRARY END** is printed each time the Macro Update Program encounters the end of the library. The two numbers indicate (1) the logical drive number and sector address of the last sector of the library currently used, and (2) the relative address of the last word on that sector which is used.

By inspecting these two words, you can determine how much of your library file has been filled.
- 4 The name of the macro being operated upon is printed. The two numbers preceding the macro name indicate where on the disk the subject macro was built. Word one indicates the logical drive number and sector address of the definition and word two indicates the relative location of where that definition begins on that sector.
- 5 An X is printed with each statement that is added to a library or macro.
- 6 Sequence numbers are printed whenever a macro text is printed.
- 7 **MACRO END** is printed whenever the Macro Update Program is through processing a definition.
- 8 If the library being worked upon is concatenated to another library, this number indicates the logical drive number and sector address of the concatenated library. If no concatenation exists, this number is zero.
- 9 The Macro Update Program prints the macro names it encounters when scanning through a library. The two numbers in front of the macro name indicate information as described in 4.
- 10 The library named in a LIB, JOIN, or CONCAT statement must have been defined previously with an *DFILE control statement and initialized with a BUILD statement.
- 11 This message is printed when the Macro Update run has been completed. It does not imply successful completion; messages prior to this one may indicate error conditions.

• ADD A MACRO TO MOVE THE CONTENTS OF A SPECIFIED INDEX REGISTER TO
 • ANOTHER SPECIFIED INDEX REGISTER
 • CALLING FORMAT IS
 LABEL LOADX FROMX,TOX
 WHERE 'FROMX' IS THE INDEX REGISTER WHOSE CONTENTS ARE MOVED TO THE
 INDEX REGISTER 'TOX'.

(11) UPDATE COMPLETED

```

(1) The library named in a BUILD statement must have been defined previously with an *DFILE control statement.

(2) The NAME statement is required and may specify parameter names to be used in a subsequent definition.

(3) **LIBRARY END** is printed each time the Macro Update Program encounters the end of the library. The two numbers indicate (1) the logical drive number and sector address of the last sector of the library currently used, and (2) the relative address of the last word on that sector which is used.

By inspecting these two words, you can determine how much of your library file has been filled.

(4) The name of the macro being operated upon is printed. The two numbers preceding the macro name indicate where on the disk the subject macro was built. Word one indicates the logical drive number and sector address of the definition and word two indicates the relative location of where that definition begins on that sector.

(5) An X is printed with each statement that is added to a library or macro.

(6) Sequence numbers are printed whenever a macro text is printed.

(7) **MACRO END** is printed whenever the Macro Update Program is through processing a definition.

(8) If the library being worked upon is concatenated to another library, this number indicates the logical drive number and sector address of the concatenated library. If no concatenation exists, this number is zero.

(9) The Macro Update Program prints the macro names it encounters when scanning through a library. The two numbers in front of the macro name indicate information as described in (4).

(10) The library named in a LIB, JOIN, or CONCAT statement must have been defined previously with an *DFILE control statement and initialized with a BUILD statement.

(11) This message is printed when the Macro Update run has been completed. It does not imply successful completion; messages prior to this one may indicate error conditions.

Errors and Warnings

During the assembly process, the Macro Assembler checks for source program errors. If an error is detected, an error flag or an error code and message will be printed. If a questionable instruction is encountered, it is flagged with a warning flag, Q. Errors in the Macro Update Program are detected by the DM2 Disk Utility Program or the MPX Disk Management Program.

Macro Assembler Sign-Off Message

At the end of each assembly, the Macro Assembler indicates the number of errors and warnings it encountered during that assembly. The message reads:

XXX ERROR(S) AND XXX WARNING(S) IN ABOVE ASSEMBLY.

XXX represents a three-digit decimal number.

Macro Assembler Warning Flag

If the source program contains certain questionable instructions, the Macro Assembler will interpret and process them and flag them with a Q. For example, the statement MDX L PLACE is assembled as MDX L PLACE,0 and is flagged with the warning indicator. Warning flags are not counted as errors and will not prevent the execution of the object program. It is suggested that you check to make sure that the Macro Assembler has performed the task that you really wanted it to do on each statement flagged with a Q.

Macro Assembler Error Detection Codes

During the assembly process, the Macro Assembler checks the source program for errors. Error and warning flags are printed to the left of the label field of each source statement that is in error or is questionable. For a complete description of the listing format of an assembly, see the 1130 DM2 Programming and Operator's Guide, Order Number GC26-3717, or the 1800 Error Messages manual, Order Number GC26-3727.

See Table 1 for an explanation of the error flags and Table 2 for a listing of the Macro Assembler error messages and their meanings.

Macro Update Program Error Messages

When the DM2 Disk Utility Program or the MPX Disk Management Program encounters an error in the Macro Update Program, one of the error messages in Table 3 is printed.

Table 1. Error Flags

Flag	Cause and Macro Assembler Action
A	- Address Error. Attempt made to specify, directly or indirectly, a displacement field outside range of -128 to +127. Displacement is set to zero. - Invalid reference to CE Core in a long form instruction. Address field is set to zero. (1800 only)
C	Condition Code Error. Character other than +, -, Z, E, C, or O detected in first operand of short branch or second operand of long BSC, BOSC, or BSI statement. Displacement is set to zero.
F	Format Code Error. Character other than L, I, X, or blank detected in column 32, or L or I format specified for an instruction valid only in short form, or I format specified when not allowed. Instruction processed as if L format were specified, unless that instruction is valid only in short form, in which case it is processed as if the X format were specified.
L	Label Error. Invalid symbol detected in label field. Label is ignored.
M	Multiply Defined Label Error. Same symbol encountered in label fields of two or more statements. First occurrence of symbol in label field defines its value; subsequent occurrences of symbol in label field are ignored and cause an M error flag to be printed.
O	Op Code Error. - Invalid op code. Statement is ignored and address counter is incremented by 2. - ABS used when *COMMON is used to define FORTRAN common table. Statement is ignored. (1800 only) - ISS, ILS, ENT, LIBR, SPR, EPR, or ABS incorrectly placed. Statement is ignored.
Q	Warning. A statement whose syntax is questionable was encountered.
R	Relocation Error. - Expression does not have a valid relocation. Expression is set to zero. - Non-absolute displacement specified. Displacement is set to zero. - Absolute origin specified in relocatable program. Origin is ignored. - Non-relocatable operand in END statement of relocatable mainline program. Columns 9-12 are left blank; entry is assumed to be relative zero. - Non-absolute operand specified in BSS or BES. Operand is assumed to be zero. - ENT operand is non-relocatable. Statement is ignored. - Invalid reference to CE Core. Address field is set to zero. (1800 only) - Invalid reference to a symbol defined in a COMMON area. Address field is set to zero. (1800 only)
S	Syntax Error. - Invalid expression, for example, invalid symbol, adjacent operators, or illegal constant. Expression is set to zero. - Illegal character in record. If illegal character appears in expression, label, op code, format, or tag field, additional errors may be caused. - Main program entry point not specified in END operand. Columns 9-12 are left blank; entry is assumed to be relative zero. - Incorrect syntax in EBC statement (such as no delimiter in column 35, or zero character count). Columns 9-12 are not punched; address counter is incremented by 17. - Invalid label in ENT or ISS operand. Statement is ignored.
T	Tag Error. Column 33 contains character other than blank, 0, 1, 2, or 3 in instruction statement. Tag of zero is assumed.
U	Undefined symbol. Undefined symbol in expression. Expression is set to absolute zero.
1130 ONLY	
W	X or Y coordinate, or both, not within the specified range, or invalid operand. Operand set to zero.
X	Character other than R or I in column 32, or character other than D or N in column 33. Field set to zero.
Z	Invalid condition in a conditional branch or interrupt order. Condition bits in first word set to zero.

● Table 2. Macro Assembler Error Codes and Messages

Error Code and Message	Cause
A01 MINIMUM W.S. NOT AVAILABLE (1130) ASSEMBLY TERMINATED	Working Storage (for DM2) or Batch Processing Working Storage (for MPX) available is less than the number of overflow sectors specified plus one.
A01 MINIMUM W.S. NOT AVAILABLE... (1800) ASM TERM.	
A02 SYMBOL TABLE OVERFLOW (1130) ASSEMBLY TERMINATED	Number of sectors of symbol table overflow is greater than the number of overflow sectors specified.
A02 SYMBOL TABLE OVERFLOW... (1800) ASM TERM.	
A03 DISK OUTPUT EXCEEDS W.S.	Intermediate output in pass 1 or final disk system format output in pass 2 is larger than Working Storage (for DM2) or Batch Processing Working Storage (for MPX) minus the number of overflow sectors specified.
A04 SAVE SYMBOL TABLE INHIBITED	With *SAVE SYMBOL TABLE option specified: ● Program in relocatable assembly. ● Program contains an assembly error. ● Source program causes more than 100 symbols to be present in the System Symbol Table.
A05 XXX ERRONEOUS ORG, BSS, OR (1130) EQU STATEMENTS IN ABOVE ASSEMBLY	XXX is the number of ORG, BSS, BES, and/or EQU statements that were undefined in pass 1. At the end of pass 1, these erroneous statements are printed on the list printer. If the error was due to forward referencing, it will not be detected during pass 2.
A05 ERRONEOUS STMT ON (1800) PASS ONE.	Errors were detected during pass one. This warning message is printed at the end of pass one.
A06 LOAD BLANK CARDS	A card containing a nonblank column in columns 1-71 has been read while punching the symbol table (as a result of an *PUNCH SYMBOL TABLE control statement).
A07 ABOVE CONTROL STATEMENT (1130) INVALID	An invalid control statement has been read by the Macro Assembler. The control statement is ignored and the assembly is continued.
A07 INVALID CTRL STATEMENT (1800)	
A08 MACLIB UNDEFINED	The Macro Assembler has been asked to process a SMAC statement and either no *MACLIB control statement was previously read, or the name on the *MACLIB statement is not found in a disk area search. The library named in the *MACLIB statement has a library concatenated to it and this library could not be found.
A09 PARAMETER LIST OVERFLOW (1130) ASSEMBLY TERMINATED	A call to a macro exceeds the space specified in the N2 field of the *OVERFLOW SECTORS control statement used with this assembly. If the *OVERFLOW SECTORS control statement was not used or if the N2 field was not specified, the Macro Assembler assumes the value of the N2 field to be zero.
A09 PARAM LIST OVFL0 (1800)	
A10 MACRO AREA OVERFLOW (1130) ASSEMBLY TERMINATED	An attempt was made to define a temporary macro and either the N3 field of the *OVERFLOW SECTORS control statement was not specified, or the space specified by N3 was not large enough, or the macro library was exceeded.
A10 MACRO LIBR OVFL0 (1800)	
A12 NEST LEVEL EXCEEDS 20 ASSEMBLY TERMINATED	A macro call exceeded the allowable nest level limit of 20.
A21 *LEVEL CONTROL STATEMENT MISSING	The program listed above was assembled as an ISS subroutine without the required *LEVEL control card. (1130 only)
A22 INVALID LIST DECK OPTION ASSEMBLY TERMINATED	An attempt was made to punch macro statements in two pass mode. (1130 only)
A40 MAIN PROG NO NAME	Mainline program being assembled has no name specified on a // ASM statement. (1800 only)
A41 // CARD READ	A Supervisor control statement has been read by the Macro Assembler. The Macro Assembler has passed this statement along to the Supervisor before terminating the assembly. Loading and DMP operations are inhibited. (1800 only)
A42 ABSOLUTE REENTRANT PROG	A non-relocatable program has been specified as reentrant. (1800 only)
A43 INVALID SFRLE FILE	When loading the source deck via *SFRLE, the file was truncated due to insufficient sector allocation. (1800 only)
A44 LIT TBL OVFL0	The size of the literal table as specified on the fourth parameter of the *OVERFLOW SECTORS control statement was too small. (1800 only)
A46 XREF DATA OVFL0	VCORE was too small to sort and merge the data for building the cross-reference table. (1800 only)

Table 3. Macro Update Program Error Messages

Error Code and Message	Cause and Corrective Action
D100 LIBRARY NOT FOUND	Library named on a LIB, BUILD, JOIN, or CONCAT statement could not be found on drives currently in use. If LIB, BUILD, or JOIN statement, all statements are ignored until the next LIB, BUILD, or ENDUP statement is encountered. If CONCAT statement, processing continues with the next control statement. Correct the name field in the statement in error, or change the // JOB statement to include the drive on which the named library resides, or define the macro library using an *DFILE or *STOREDATA control statement.
D101 INVALID SUBFIELD COL XX	If on an INSERT or DELETE statement, the sequence number was incorrectly specified, that is, it was negative, or non-numeric, or sequence numbers were reversed. If on a SELECT statement, an incorrect parameter was specified. Processing continues with the next control statement. If on a NAME statement, an invalid parameter was detected. Processing continues with next LIB, BUILD, or ENDUP statement. XX indicates the column in which the error was found. Correct the error and rerun the portion of the job affected.
D102 ILLEGAL REQUEST	An invalid control statement was detected, an INSERT or DELETE statement was not preceded by an UPDATE or RENAME statement, or on an 1130, request was made for output to paper tape or to a pack configured for paper tape. Processing continues with the next control statement. Correct the error and rerun the portion of the job affected.
D103 LIBRARY OVERFLOW	The library last specified by a LIB or BUILD statement does not have enough room to perform the operation. If on a JOIN or an ADD statement, the operation is suppressed and the library is restored to its previous state. If on an INSERT statement, the statements listed prior to the message were the only ones that could be included. Processing continues with the next LIB, BUILD, or ENDUP statement. Additional space can be obtained in the current library by purging unneeded macros or deleting unneeded statements. If this is not possible, define a larger library using an *DFILE or *STOREDATA control statement, join the old library to a new one, and delete the old library. Once the additional space has been obtained, rerun the portion of the job affected. If on an INSERT, it may be necessary to alter your INSERT control statement as the statements in the macro library may have been resequenced.
D104 MACRO NOT FOUND	The macro name specified on an OUTPUT, PURGE, RENAME, or UPDATE statement could not be found in the library being processed. Processing continues with the next control statement. Correct the macro name on the statement in error, or specify the correct macro library and rerun the portion of the job affected.
D105 SEQUENCE NUMBER NOT FOUND	The sequence number on an INSERT or DELETE statement was out of the range of the macro and could not be found or the sequence numbers on multiple INSERT and/or DELETE statements for the same macro were out of order. Processing continues with the next control statement. Place a correct sequence number on the statement in error and rerun the portion of the job affected.
D106 LIBRARY NOT SPECIFIED	An attempt was made to operate on a macro without specifying a macro library. Processing continues with the next LIB, BUILD, or ENDUP statement. Place a LIB or BUILD statement before the statement in error and rerun the portion of the job affected.
D107 SPILL OVERFLOW	Macro text insertions have caused the capacity of Working Storage spill to be exceeded. Processing continues with the next LIB, BUILD, or ENDUP statement. Correct the sequence numbers in the unprocessed INSERT statements, if necessary, and rerun these statements. It may be necessary to define additional disk drives to provide adequate Working Storage.
D108 CONTROL STATEMENT READ	An * or // statement has been read and the MUP run is terminated. On the 1800, control is passed to the Supervisor which will begin processing with the next // JOB statement. On the 1130 control is returned to the Supervisor for a // statement or to DUP for an * statement.
D109 NAME STATEMENT NOT FOUND	The operation attempted requires a NAME statement and one has not been processed following the last LIB or BUILD statement. Processing continues with the next LIB, BUILD, or ENDUP statement. Insert a NAME statement and rerun the part of the job that was affected.

Table 3. Macro Update Program Error Messages (Continued)

Error Code and Message	Cause and Corrective Action
D110 INVALID NAME	The name field on a LIB, BUILD, JOIN, CONCAT, UPDATE, ADD, PURGE, RENAME, or OUTPUT statement was left blank, the name specified was invalid, or the apostrophes are improperly placed. If on a LIB, BUILD, or JOIN statement, processing continues with the next LIB, BUILD, or ENDUP statement. If on a CONCAT, UPDATE, ADD, PURGE, RENAME, or OUTPUT statement, processing continues with the next control statement.
D112 NONBLANK CARD READ. ENTER BLANK CARDS	A nonblank card has been read by a 1442-6 or -7 during a punch operation. Remove stacked input from hopper, NPRO nonblank cards, place blank cards followed by NPRO cards and stacked input in the hopper, and press reader START and for the 1130 press program START.
D116 LIBRARY NOT INITIALIZED	Library named on a LIB, JOIN, or CONCAT statement has not been initialized previously. If on a LIB, or JOIN statement, processing continues with the next LIB, BUILD, or ENDUP statement. If on a CONCAT statement, processing continues with the next control statement. Initialize the library with a BUILD statement, and rerun the portion of the job affected. If on a BUILD statement, the library specified was not a data file. Correct the BUILD statement and rerun the portion of the job affected.
D117 INVALID PARAMETER	On a NAME statement, more than 20 parameters were specified. If during the processing of a macro, a parameter has been detected which was not defined in the NAME statement or a parameter greater than one character was used in the format or tag field. If during an OUTPUT operation, the operation is aborted and processing continues with the next control statement. If during a listing operation, this is a warning message and the invalid parameter is printed as //N where N is 1-20. (Note: N may be truncated if the field size is exceeded.) If on OUTPUT, correct the NAME statement and rerun the portion of the job affected.

This page intentionally left blank.

Appendix A: General Examples of Macros and 1130 DM2 Macro Assembler Features

The following group of macros and the examples of their use are intended to demonstrate how macro instructions can be used to simplify assembler-language programming. If all these macros were defined in your system, then you could use two new statements--the READ statement and the WRITE statement--to accomplish all the programming normally required to effect input and output on an 1130 system having a disk, a 1442 card read punch, and a 1403 printer. When you issue a READ or WRITE macro, you need specify only the name (DISK, CARD, or PRINT) of the device you want to use, the name of the I/O area, and, if you want, the name of your error-handling program. This system of macros then issues calls to the appropriate I/O control subroutines, handles data conversion and blocking, and, at your option, handles error checking and retries.

You could, of course, expand this set of macros to include all I/O devices supported by the 1130 system; you could also write a similar set of macros to simplify I/O programming on the 1800 system.

Refer to the 1130 Subroutine Library manual, Order Number GC26-5929, for a complete description of the 1130 I/O control subroutines (DISKN, CARD1, and PRNT3) referred to in these macros.

The first part of this sample program (until the *MACRO UPDATE statement) is a FORTRAN program that builds a one sector file of one-word integers having the value 1 through 320. This is necessary to handle the data file in the sample program that follows it.

```

- *DFILE Statement 47-48,61-62
- *MACLIB Control Statement 2,22
- *MACRO UPDATE Control Statement 47
- *OVERFLOW SECTORS Control Statement 1-2
- *STOREDATA Statement 47-48
- *, Used to Designate Comment Statements 5
- **LIBRARY END** 61-62
- **MACRO END** 61-62
- @ Sign 48
- \$ Sign 48
- + Sign
 - used as a macro expansion indicator, 7
 - used to indicate a positive number, 27
- # Sign 48

- ADD Statement 51,52-53
- Additional Records, Continuing
 - Calls to 12-13
- AGO Pseudo-Op
 - use in label and blank parameter checking, 30
- AGOB Pseudo-Op 17-18
 - special considerations in use, 18-19
- AIF Pseudo-Op 15-16,17
 - restriction of use, 29-30
- AIFB Pseudo-Op 15-16
 - restriction of use, 29-30
 - special considerations in use, 18-19
- Amperсанд, Used as a Concatenator 23
 - example, 24-25
- ANOP Pseudo-Op 19-20
- Apostrophe
 - restriction of use in the name of a stored macro, 5
 - used in automatic name generation, 22-23
- Assemble if Back Pseudo-Op
 - See AIFB Pseudo-Op.
- Assemble if Pseudo-Op
 - See AIF Pseudo-Op.
- Assembler Language, A symbolic programming language.
- Assembler-Language Statement, An assembler-language instruction or a pseudo-operation.
- Assembler-Language Instruction, An instruction that the Macro Assembler can translate into exactly one machine-language instruction.
- Automatic Label Generation
 - See Automatic Name Generation.
- Automatic Name Generation 1,22-23.
 - The method by which different labels can be generated during each expansion of a macro instruction in the same assembly.
 - special requirements on its use in nested definitions, 57-58
- Blank and Label Parameter Checking
 - Using AGO 30
- BUILD Statement 48
- Calling
 - macros, 7
 - Macro Update Program, 47
- Calls
 - continuation of to additional records, 12-23
 - macro, 7,12
- Character String
 - in message generation, 11-12
 - substitution for a parameter, 10-11
- Characters, Special 6,10,47
- Checking
 - for blank parameters, 28-29
 - for label and blank parameters using AGO, 30-31
 - for unspecified parameters, 17-18
 - for unspecified parameters, a macro, 34
- Comma
 - lack of use in continuation of NAME statement, 52
 - use in a macro instruction, 7-8
- Comments
 - designating, 5,58
 - listed within the expansion, 25
 - See also Remarks.
- CONCAT Statement 49-50
- Concatenation 2. The process by which two things (such as two parts of an instruction, or two macro libraries) are logically joined together.
 - of macro instructions, 23-25
 - of macro libraries, 49-50
- Concatenating a Multiplicity of Libraries, 49-50
- Concatenators
 - ampersand, 23
 - CONCAT statement, 49-50
 - period, 23
- Conditional Assembly Pseudo-Ops 15-18
- Continuing Calls to Additional Records 12-13
- Control Statement 47. A statement that provides instructions to some part of the Disk Management Program or Disk Utility Program.
 - continuation of, 47
- Copying an Existing Library 49
- Core Storage
 - See Main Storage.

Creating a Language 1,37-45
 DC-Generating Macro 34-35
 Defining
 a language, 1
 a macro, 1,6
 a macro during a Macro Update Run, 51-53
 a macro instruction, 5
 Definition Prototype Statement 5-6,53.
 The statement in a macro definition that specifies the op code and parameters of the macro.
 printing of, 6
 DELETE Statement 55-56
 in automatic name generation in nested definitions, 57-58
 in renaming a library, 51
 in updating a library, 50
 Deleting a Macro from a Library 53
 Deleting Statements from a Macro 55-56
 Designating Comments 5,58
 Disconnecting Concatenated Libraries 50
 Disk Management Program (DMP) 47. A group of 1800 MPX disk utility and maintenance programs that operate under control of the Batch-Processing Monitor Supervisor.
 Disk Monitor System, Version 2 (DM2), The second version of an operating and programming system that provides for the continuous batch-processing operation of the 1130.
 estimating size required, 1-2
 initializing, 2,47-48
 Disk Utility Program (DUP) 47. A group of 1130 disk utility and maintenance programs that operate under control of the Supervisor.
 Division Operator 27
 DMP
 See Disk Management Program.
 DM2
 See Disk Monitor System, Version 2.
 DUP
 See Disk Utility Program.
 EJCT Pseudo-Op 15,17,18
 END Statement 15,17,18
 ENDUP Statement 58-59
 EQU Statement 20
 symbolic tag field in, 27
 Error Flags 4,63-64
 Error Messages 4,63,65-67
 Estimating
 size of N2, 2
 size of N3, 2
 Expansion 7. The coding generated when the Macro Assembler encounters a macro instruction; also, the process of generating this coding.
 Field Specifications on Macro Update Control Statements 47

Flags

error, 4,63-64
 warning, 4,63

HDNG Pseudo-Op 15,17,18

Indirect Parameter Substitution 26,32-33.

The feature of the Macro Assembler that allows different parameters on the macro call statement to be substituted for a specific parameter in the macro expansion, depending on some condition to be inspected during assembly.

Initializing Disk Space 2,47-48

INSERT Statement 54,55

in automatic name generation in nested definitions, 57-58
 in renaming a library, 51
 in updating a library, 50

Inserting Statements in a Macro 54-55,56
 restrictions on, 55,56

Insufficient Parameter Names 52

JOIN Statement 49-50

Joining Macro Libraries
 logically, 2,22,49-50
 physically, 49-50

Label Field Parameters 8

Label and Blank Parameter Checking
 Using AGO 30

Label Generation

 See Automatic Name Generation.

Language Creation 1,37-45

Library

 See Macro Library.

LIB Statement 48

List Control Pseudo-Ops 6

LIST Pseudo-Op 15,17,18

Listing of

comment statements, 6
 macro calls, 25
 macro libraries, 56-57

LNAME 3,48

Logically Joining Macro

Libraries 2,22,49-50

MAC Statement 5,25,51,53

Macro Assembler, The translating program that accepts as input assembler-language instructions, pseudo-operations, and macro instructions.

error flags, 63-64

error messages, 63-65

language, 37-45

main-storage requirements, 3,4

performance, 4

purpose, 1

sample programs, 33-35,69-84

sign-off message, 63

warning flag, 63

Macro Calls 7,12
 continuation to additional records, 12
 listing of, 6
 nested, 3,10,23,26,32

Macro Definition 1,2. A sequence of instructions that define the op code and parameters of a macro instruction and the coding to be generated when the macro is assembled.
 during a macro update run, 51-53
 nested, 3

Macro Expansion 7

Macro instruction 1. A source program statement that, when encountered by the Macro Assembler, causes a predefined sequence of statements to be assembled.
 defining, 5
 using, 7

Macro Library 3. A collection of macro definitions, saved on disk, that can be used by any program that references that library.
 copying, 49
 disconnecting, 50
 initializing, 3
 joining logically, 49-50
 joining physically, 48-49
 maintaining, 3
 naming, 47-48
 specifying, 48

Macro Name 1,5,22

Macro Parameter Substitution 32-33

Macro Update Program 4,47-62. A DMP or DM2 program that allows you to initialize and maintain macro libraries.
 calling, 47
 control statement sequencing, 59
 error messages, 65-67
 making efficient use of, 59-60
 sample program, 61-62

Macros
 stored, 1,2-3
 temporary, 1-2

Main Storage Requirements
 1130, 3-4
 1800, 4

Making Efficient Use of the Macro Update Program 59-60

MEND Statement 5,51,53
 termination of AGO and AGOB search, 17
 termination of AIFB search, 16

Message Generation 11-12

Message Macro 34

Messages, Error 4,63,65-67

Move Macro 34

MPX
 See Multiprogramming Executive Operating System.

Multiple Concatenation 49-50

Multiprogramming Executive Operating System (MPX), An operating system for the 1800 that can control processes and provide multiprogramming and background processing.

MUP
 See Macro Update Program.

N2 1,2

N3 1,2

Name
 of a library, 47-48
 of a macro, 1,5,22
 of a parameter, 5-6,7,52

Name Generation, Automatic 1,22-23,57-58

NAME Statement 47,51-52
 continuation of, 51-52
 used in the sample program, 61-62

Name Subfield Left Blank on AIF and AIFB Statements 16

Nested Macro Calls 3
 in automatic name generation, 23
 in continued calls, 32
 in definitions defined during a macro update run, 53
 in indirect parameter substitution, 26,32
 passing a set of parameters, 10
 restrictions on, 3

Nested Macro Definitions 3. Macro definitions that are defined so that a call to one occurs within the expansion of the other.
 SELECT N considerations, 57-58

Obtaining a Listing of Macro Libraries 56-57

Omitting
 name subfields on AIF and AIFB statements, 16
 operand on AGO and AGOB statements, 17
 parameters, 8-9

Op Code 5. That field of an assembler-language statement that specifies the operation to be carried out by the CPU.

Operand Field 6

Operand Left Blank on AGO and AGOB Statements 17

Optional Remarks 25

OUTPUT Statement 54

Parameters
 blank, checking for, 28-29
 in a macro instruction, 1
 indirect substitution, 26,32-33
 insufficient names, 52
 label field, 8
 macro to check for unspecified parameters, 34
 name, 5-6,7
 omitting, 8-9
 substituting a character string for, 10-11
 substitution, 6,32-33
 unspecified, checking for, 17-18

Performance of the Macro Assembler 4

Period
 example of use as a concatenator, 24
 in DEC and XFLC statements and concatenation, 25
 used as a concatenator, 23
 used to designate comments, 58
 Physically Joining Macro Libraries 48-49
 Plus Sign,
 used as a macro expansion indicator, 7
 used to indicate a positive number, 27
 Printing
 definition prototype statements, 6
 inhibition of, 6,56-57
 sequence numbers, 6,55,61-62
 Pseudo-Operation 3. An assembler-language statement that provides information for the Macro Assembler rather than generating executable code.
 AGO, 17-18
 AGOB, 17-18
 AIF, 15-16,17
 AIFB, 15-16
 ANOP, 19-20
 conditional assembly, 15-17
 EJCT, 15,17,18
 END, 15,17,18
 HDNG, 15,17,18
 LIST, 15,17,18
 MEND, 15,17,18
 PURG, 15,17,18
 SET, 20-22
 SPAC, 15,17,18
 Pseudo-Ops
 See Pseudo-Operation.
 Punching Source Statements 54
 PURG Statement 22
 PURG vs. PURGE 54
 PURGE Statement 53-54

 Reclaiming Library Space 53-54
 Records, Continuing Calls to Additional 12-13
 Remarks
 optional, 25
 retaining, 5
 RENAME Statement 51
 Renaming a Macro in a Library 51
 Restrictions
 on AIF, AIFB, and SET pseudo-ops, 29-30
 on inserting statements, 55,56
 on nested macro calls, 3
 on nested macro definitions, 3
 on parameter names, 6,11,51
 Retaining Remarks 5

 Sample Programs
 creating a language, 37-45
 Macro Assembler, 33-35
 Macro Update Program, 61-62

 1130 Macro Assembler, 69-84
 SELECT Statement 56-57
 SELECT N as Used with Automatic Name Generation in a Nested Definition 57-58
 SELECT P as Used with NAME Statement 59
 Semicolon, Used in Indirect Parameter Substitution 26,32
 Sense Switch 2 6,56-57
 Sequencing MUP Control Statements 59
 Sequence Numbers, Printing of 6,55,61-62
 SET Pseudo-Op 20-22
 restriction of use, 29-30
 symbolic tag field in, 27
 Sign-Off Message 63
 Signs,
 @, 48
 \$, 48
 +, 7,27
 #, 48
 SMAC Statement 5,25,51,53
 Source Statements, Punching of 54
 Space, Reclaiming 53-54
 SPAC Pseudo-Op 15,17,18
 Special Characters 6,10,47
 Special Requirements on the Use of Automatic Name Generation in Nested Definitions 57-58
 Specifying the Macro Library 48
 Statements
 deleting from a macro, 55-56
 inserting into a macro, 54-55,56
 See also the name of a particular statement or the function it performs.
 Stored Macro 1,2-3,5. A macro instruction that is saved on disk and can be used by any program.
 Substituting a Character String for a Parameter 10-11
 in message generation, 1-12
 Substitution
 indirect parameters, 26,32-33
 parameter, 6,32-33
 Symbol Table, for 1130 DM2 3-4
 Symbolic Tag Field 27-28

 Tag Field, Symbolic 27-28
 Temporary Macro 1-2,5. A macro instruction that is defined for use only during one specific assembly.
 Terminating a Macro Update Run 58-59
 Text 6,7. A list of assembler-language instructions, calls to other macros, and/or pseudo-ops to be generated when a macro call is encountered.
 Truncation of Information Following Column 71 6,10,25

Unspecified Parameter Checking 17-18
UPDATE COMPLETED 59,62
UPDATE Statement 50
Updating a Macro in a Library 50
See also DELETE Statement and
INSERT Statement.
Using a Macro Instruction 7

Warning Flag 4,63

X, Used to Designate an Addition of a
Statement to a Macro or
Library 55,61-62

YOUR COMMENTS, PLEASE...

This publication is one of a series which serves as reference sources for systems analysts, programmers and operators of IBM systems. Your answers to the questions on the back of this form together with your comments, will help us produce better publications for your use. Each reply will be carefully reviewed by the persons responsible for writing and publishing this material. All comments and suggestions become the property of IBM.

Please note: Requests for copies of publications and for assistance in utilizing your IBM system should be directed to your IBM representative or to the IBM sales office serving your locality.
